Despite the large influx of women into the labor force, the average number of hours employed adults work has remained relatively stable over time. This seems difficult to reconcile with the increased sense of time pressure that so many Americans as well as Europeans report (Robinson and Godbey, 1997). One explanation for this is that work hours have become more bifurcated over time with more people working long hours, particularly those in dual-career marriages, and more people working short hours. Hence, examining average work hours across all families may be misleading. Second, the time deficit is more easily understood as one that families rather than individuals experience. Dual-career couples spend a total of 80–100 h a week in market work relative to single-earner couples who spend about half of that in market work and thus have more time available as a family unit, for nonmarket work and leisure (Jacobs and Gerson, 2004). At the same time, dual-career and dual-earner families may be better able to afford time-saving devices and outsource nonmarket work to protect leisure time as well as time with children.

Work–Life Balance

The seemingly increased pace of life for dual-career families has shifted more attention on the ability of husbands and wives to balance their work and family lives. This is quite challenging in an era where both spouses are not only employed, but also pursuing careers that might require long hours, extended time away from home in the form of frequent travel, and irregular or rotating shifts. Indeed, the most financially lucrative and high-status careers often carry some or all of the aforementioned characteristics, as do many low-status positions with fewer benefits (Presser, 1994). While work life is demanding for both working and middle class families, contemporary family life is also complex when marriages are less stable and the expectations to invest lots of time in both marriages as well as children are very high. Juggling the often competing demands of work and family life in a dual-career marriage is a source of great stress for dual-career families, especially those with children. The past two decades marked a period of

landmark legislation in the United States to address the strains felt by working families with the passage of the Federal and Medical Leave Act in 1993, which provides employees up to 12 weeks unpaid, job-protected leave in the event of a variety of pressing family or medical situations. Since that time, there have been efforts to expand that legislation as well as introduce additional legislation that would ease work and family strains, including universal health care adopted by many other Western nations. Western European nations, particularly the Nordic countries, have some of the most family-friendly policies, including more stringent regulations on employment hours, paid mandatory parental leave, and high-status part time work with substantial health and retirement benefits. Those countries also have greater occupational sex segregation than the United States (Gornick and Meyers, 2005).

Despite the movement toward gender parity in both market and nonmarket work, the implications of combining work and family responsibilities are quite different for men than for women. Given that responsibility for tending the home and caring for children still rests predominantly on women's shoulders, and that the expectations for investing lots of time in children are high, it is not surprising that wives tend to make more sacrifices in their careers for family life than husbands do (Bianchi et al., 2006; Hays, 1996). In fact, if anything, combining marriage, parenthood, and a career is beneficial for men (Nock, 1998; Waite, 1995). Married men tend to earn more and have higher status jobs relative to unmarried men. Further, the birth of children results in longer work hours and greater earnings for men (Nomaguchi and Milkie, 2003). The pattern of greater earnings and status for married men characterizes most of the developed world (Schoeni, 1995). Husbands, particularly upon the birth of a child, may have a greater motivation to assume the role of provider, whereas wives may also desire or feel pressure to help support their husbands in the provider role (Hays, 1996). The persistent gender gap in pay in both the United States and developed countries also helps to perpetuate a model where husbands remain primary breadwinners and wives' careers are secondary. Heavily investing in one's career also seems to pay off for men by making them more attractive mates and once they are married, their marriages are more stable (Bergstrom and Schoeni, 1996).

In contrast to married men, married women's career attainments generally do not result in greater marital stability or earnings, especially when they are mothers. Most women reduce their employment hours when they have children and only about a third of women with very young children work full time, year round (Bianchi et al., 2006). This, in turn, results in reduced earnings in what has been coined the 'motherhood wage penalty' of a 7% reduction in earnings for each child, with larger penalties for married women than unmarried women. The motherhood wage penalty is an additional reduction in earnings to mothers beyond what would be predicted with the lost job experience (Budig and England, 2001). When married women do not have children, they do a greater share of the nonmarket work, even when they are employed similar hours as their husbands (Sayer et al., 2009). Hence their penalty can be conceptualized in workloads rather than earnings. Marriage and parenthood may therefore enhance a man's career attainment, while weakening a woman's. In light of the fact that most married couples are dual earners and most of these couples have children, this means that most dual-earner couples are not in practice dual-career couples where the career trajectories are equally valued or supported. Most dual-career marriages are those where men's careers are primary and women's are secondary (Becker and Moen, 1999).

Earning Arrangements among Dual-Career Couples

Although it is still normative for men to be the primary earners even among dual-earner couples, trends over the past 40 years suggest that this model may have an uncertain future. In about a quarter of couples, wives contribute to family income at equal levels as their husbands, more than double the proportion of equal earners in 1970. Wives who are primary earners have also increased dramatically over the past four decades, although rates are still relatively low, especially if a strict standard of primary breadwinning is applied rather than crude measures where wives earn only a nominal amount more than their husbands (Raley et al., 2006). The trends are almost entirely linear, with an increasing trend toward greater diversity in earning arrangements and arrangements where wives have greater earning power.

Earning arrangements have a curious relationship with housework and the care of children. One might expect that as wives have greater earning power in the relationship and/or less time available to do housework or care for children relative to their husbands, that husbands' time spent in family work would steadily increase. Instead, there is a curvilinear relationship between earnings and housework whereby wives with much higher earnings than their husbands often do as much or more housework than their husbands who earn much less. The earning arrangements where men tend to do the most housework are those where husbands and wives are equal earners (Bittman et al., 2003). Similarly, men in dual-career couples with children do more of the routine, or the day-to-day child care when their wives have greater earning power when compared with men whose wives have less earning power. At the same time, dual-career wives who earn much more than their husbands still spend substantial amount of time in child care, typically surpassing that of their husbands. In other words, their husbands do more child care than other husbands, but still not more than their wives (Raley et al., 2012).

Work Schedules among Dual-Career Couples

The movement toward a service economy in many Western countries has had major implications for work schedules, and consequently, working families in particular. The service economy demands more workers be available for evening, night, and weekend shifts. In over 25% of dual-earner couples in the United States, at least one spouse works a nondaytime shift (Presser, 1994). Shifts are also increasingly variable, meaning workers may have fewer windows of time that are consistently available for family or leisure. Moreover, many dual-earner couples are dealing with a situation where their work schedule does not overlap with that of their spouse. When couples do not work at the same time, they have limited time to spend with each other or together as a family with children if one spouse is

at home while the other is at work. With nonoverlapping or rotating shifts, family dinner may have to be replaced with a family breakfast or forgone altogether (Presser, 1989, 1994).

Although there are negative implications for shift work among dual-career couples in the way of reduced couple time, decreased marital stability, and even negative health implications such as irregular or interrupted sleeping rhythms, there are also implications for greater gender equality (Presser, 1994; Wight et al., 2008). The more time that husbands are at work while their wives are simultaneously working outside the home, the more likely husbands are to spend time doing housework. In particular, they are more likely to do female-typed tasks, such as cooking and cleaning. Similarly, when wives are at home during the same period of time that their husbands are working, wives also spend more time doing housework traditionally done by women. This implies that when wives are not available to do certain housework tasks, their husbands will do them. An economy that increasingly requires irregular, nonstandard, and rotating shifts may indirectly result in a narrowed gender gap among dual-career couples. In dual-career couples where both spouses work nonstandard schedules and are professionals or managers, the gender gap in housework is even narrower than among other nonstandard workers (Presser, 1989, 1994).

Dual-career couples who work nonstandard hours and have children may face even greater time strains on their marriage than other dual-career couples. For example, married parents who work nonstandard hours get less time with their spouses than married parents who work standard schedules. They also get less sleep. At the same time, they may have more one-on-one time with their children, and father involvement may be greater (Wight et al., 2008).

Conclusion

The meaning of marriage has shifted in recent years as same-sex couples fight for the right to marry and people look to marriage as an institution for both companionship and personal development as opposed to self-sacrifice. People are delaying and leaving marriage at higher rates than prior decades. These shifts are connected to a changing economy and changing beliefs about the appropriate roles of men and women, resulting in a now normative family type of the dual-career couple. The great diversity among dual-career couples in work scheduling and earning arrangements suggests a movement toward greater gender equity in married men's and women's allocation of time and resources.

Abstract

A marriage system is the set of rules and norms that regulate reproduction in a given human society. This article provides an overview of key concepts and general themes in the study of their evolution. The focus is on the number of spouses allowed (i.e., whether marriage is monogamous or polygamous), and the social and ecological factors associated with this aspect of the marriage system.

Definition of the Subject

A marriage system is the set of rules and norms that regulate reproduction in a given human society. This is closely linked to the set of rules and norms that shape interactions based on relatedness, the kinship system. For example, some societies draw a distinction between 'cross' and 'parallel' cousins. Your cross-cousins are the offspring of your parents' opposite-sex siblings (i.e., the children of your father's sisters and of your mother's brothers), your parallel cousins are the offspring of your parents' same-sex siblings (i.e., the children of your father's brothers and of your mother's sisters). The kinship system of one of these societies may emphasize social ties among cross-cousins over those among parallel cousins. The marriage system may stipulate marriage between cross-cousins as the preferred or prescribed form.

Both relatedness and reproduction play a role in, and are shaped by, the evolutionary process. Hence, the study of kinship and marriage systems figures prominently in biological approaches to human behavior. At the same time, it is a core topic in social and cultural anthropology. This article focuses on research on marriage systems at the interface of the two fields. A complementary treatment of kinship systems can be found in Evolution of Kinship.

Broadly, the rules and norms encoded in the marriage system pertain to two domains. One deals with definition of the socially acceptable marital arrangements: for example, whom one is allowed or not allowed to marry, whether particular categories of individuals are preferred or prescribed marriage partners, and whether multiple spouses are allowed. The other domain deals with the flow of resources at marriage. This includes the transfer of material property (e.g., dowry, where the bride's family transfers land and/or other resources to the newlywed), the provision of labor (e.g., bride-service, where the groom assists the bride's family in productive activities), and the movement of individuals (e.g., virilocal residence, where the newlywed take up residence with or near the groom's kin).

Both domains have been approached from an evolutionary perspective (see reviews and discussion in Low, 2003, 2007). Rather than attempting an exhaustive review of the literature, my aim here is to outline the general principles derived from biology that are used to frame questions about the evolution of marriage systems. To this end, I restrict the focus of the article to the rules and norms that regulate the number of spouses allowed (i.e., whether marriage is monogamous or polygamous) and their environmental correlates, both social and ecological.

Key Concepts

I begin by introducing some key concepts in the study of marriage systems, with the aim of 'unpacking' the relationship between marriage, mating, and reproduction.

What Is Marriage?

The definition of marriage system given above is intentionally vague. Clearly, this is tied to the definition of marriage itself; because of the diversity of family arrangements across human societies, development of a definition that applies universally (and that is universally accepted as such!) has proved surprisingly difficult (Holy, 1996, pp. 48–50).

For the purposes of this article marriage can be defined as a socially recognized union, normatively endorsed, between two or more individuals. This may involve (1) restrictions on sexual relations, typically allowed exclusively between spouses, and (2) the investment of resources in any children associated with the union. Resources may be 'social' (e.g., political status) or physical (e.g., material property), and they may be invested by the spouses themselves and/or by their kin. Where the resources involved are substantial, marriage may be linked to the notion of legitimacy, which serves to channel them to 'appropriate' individuals.

In these key aspects marriage is distinct from mating, irrespective of whether and to what degree pre- and/or extramarital sexual relations are tolerated (Parkin, 1997, pp. 39, 40; discussed further below). Evolutionary approaches have tended to view different marriage systems as alternative reproductive strategies; therefore, this article focuses exclusively on heterosexual marriage. The implications of homosexual marriage for anthropological theory are discussed in Levine (2008).

From a cross-specific perspective, marital unions with parental investment are analogous to nonhuman mating partnerships where mates cooperate in providing resources (e.g., food, protection) to the offspring. There are some peculiarities, however (Irons, 1983, p. 190). In addition to

cooperating in offspring provisioning, marital partners may engage in an extended pattern of reciprocal provisioning. This usually involves a division of labor between the sexes in productive activities: thus, the marital union provides access to resources that are controlled or produced by the opposite sex. Alongside reciprocal provisioning, marital partners entertain relationships of cooperation and reciprocity with several other adult individuals, while maintaining a relatively stable sexually exclusive bond with each other. In nonhuman species mate provisioning tends to be associated with copulation (e.g., courtship feeding), and transfers of resources in this context typically flow from males to females rather than reciprocally (Stevens and Gilby, 2004).

A further peculiar aspect of marital unions, compared to nonhuman mating partnerships, is the potential direct involvement of third parties (Low, 2003, 2007). For example, parents may be actively involved in selecting a spouse for their offspring; together with other kin, they may exert control over the timing of the union. By contrast, nonhuman mating partnerships are typically the outcome of direct interactions between two or more individuals. Of course, wider networks of interactions play a role in the formation of mating partnerships in any social species: for example, coalitionary alliances between males or within-group status-ranking may affect the sequence and timing of the partnerships. This, however, is distinct from the direct involvement of third parties in the arrangement of marital unions in humans.

In the evolutionary literature these peculiarities have often been portrayed as cultural 'frills' attached to the human mating system. In one view, the marriage system is simply a set of rules and norms grafted onto the mating system (e.g., Low, 2003, 2007). Another view draws on the distinction, developed for nonhuman species, between the social mating system and the sexual/genetic one. The former captures the pattern of social living arrangements (e.g., shared use of territory), the latter captures the network of sexual interactions and the resulting genetic relationships. In this view, the marriage system is analogous to the social mating system (e.g., Reichard, 2003, p. 4). As I discuss below, these and related approaches fail to account for several nuances in the interplay between marriage, mating, and reproduction.

Classification of Marriage Systems

In classifying marriage systems, a useful starting point is the distinction between two major exclusive types, based on the number of concurrent spouses allowed: 'monogamy' (individuals may be married to only one spouse at any one time) and 'polygamy' (individuals may be married to multiple spouses at any one time). Within polygamy, 'polyandry' and 'polygyny' refer to multiple concurrent spouses allowed for women and for men, respectively.

These labels derive from combination of the Greek words for single, sole (*mónos*) or many (*polús*) with the words for marriage (*gámos*), man (*anér*), or woman (*gunḗ*). Thus, polygamy is a generic term that captures any form of non-monogamous marriage, even though in the popular press it is commonly used to indicate the marriage of a man to multiple wives instead. In what follows, my use of the labels reflects the technical definitions given above, consistent with their etymology.

Classification of marriage systems as monogamous, polyandrous, or polygynous has proved particularly fruitful. This is likely because the relevant rules are readily observed, even in the absence of individual-level data on marital status; consequently, ethnographies typically include information on this aspect of the marriage system. In the Standard Cross-Cultural Sample (Murdock and White, 1969), a sample of 186 societies that is broadly representative of human cultural variation as reflected in the ethnographic record, classification of marriage systems into exclusive types yields 31 societies (17%) coded as monogamous, 2 (1%) as polyandrous, and 153 (82%) as polygynous (see discussion below). **Figure 1** shows their geographical distribution.

This classification captures variation along the synchronic dimension; additionally, there is variation along the diachronic dimension, which deals with whether individuals are allowed multiple nonconcurrent spouses over the course of their lifetime (Harrell, 1997, p. 22). In practice, the diachronic dimension relates to whether divorced and/or widowed individuals are allowed to remarry, which is not universally the case. For example, remarriage may be allowed for only one of the sexes (typically men).

Somewhat confusingly, in the evolutionary literature a marriage system that enforces monogamy but allows multiple nonconcurrent spouses is known as both 'successive monogamy' and 'successive polygamy'; the terms 'serial' and 'sequential' are also used (Mealey, 2000, p. 321). This confusion reflects the tension between the usefulness of a simple classification scheme, and its limitations in describing the relationship between the rules encoded in the marriage system, actual behavior, and the reproductive implications of each. Evolutionary approaches have been especially prone to confusion: with their focus on reproduction, they have often drawn inferences about mating behavior from information on the marriage system, which can be problematic. I return to this issue below; first, it is useful to clear up two additional potential points of confusion with the classification scheme outlined above.

One point of confusion results from the opposition of monogamy and polygamy as exclusive types. This does not imply that the two marriage systems are 'symmetric' with respect to the marital arrangements allowed: while polygamous unions are forbidden in a monogamous system, the reverse is not true; that is, monogamous unions are of course allowed in a polygamous system (discussed below).

The other point of confusion is that the terms 'polygyny' and 'polyandry' are not used consistently in the anthropological literature. Polygyny generally refers to systems where multiple concurrent spouses are allowed for men but not for women, whereas polyandry is often used for systems where multiple concurrent spouses are allowed for women, even when they are not forbidden for men. The rationale appears to be that in these so-called polyandrous societies multiple concurrent spouses are customary for women, but they are only occasional occurrences for men (discussed below). Terms that more accurately describe these scenarios ('polygynandry' or, better, 'polyandrogyny') are used rarely and inconsistently in anthropology.

Figure 1 Distribution of marriage systems across societies in the Standard Cross-Cultural Sample (Murdock, G.P., White, D.R., 1969. Standard cross-cultural sample. Ethnology 8 (4), 329–369.). Data from variable 79 (White, D.R., Burton, M.L., Divale, W.T., Gray, J.P., Korotayev, A., Khaltourina, D., n.d. Standard Cross-Cultural Codes. From: http://eclectic.ss.uci.edu/drwhite/courses/SCCCodes.htm (retrieved 31.08.07.)). This variable captures the social composition of the prevailing form of family organization, with monogamy defined in terms of the prohibition or disapproval of polygyny (Murdock, G.P., Wilson, S.F., 1972. Settlement patterns and community organization: cross-cultural codes 3. Ethnology 11 (3), 254–295.). The two categories for polygynous marriage are collapsed (limited polygyny, i.e., less than 20% of men married to plural wives, and general polygyny, i.e., more than 20% of men married to plural wives).

Marriage, Mating, and Reproduction

We can now return to the issue we touched on in the preceding two sections, of how to best characterize the interplay between marriage, mating, and reproduction. A general framework includes four nested levels. At one end is the marriage system, defined above as the set of rules and norms that regulate reproduction. This maps onto the actual pattern of marital arrangements. In turn, this maps onto the actual pattern of mating interactions, both within and outside of marriage. A final distinction is between mating behavior and the genetic level: not all sexual interactions result in the production of children, through a host of mechanisms ranging from sperm competition (*see* Human Mate Choice, Evolution of) to contraception.

We can illustrate this general framework with reference to two fictitious societies. In one society men are allowed multiple concurrent spouses, but remarriage is forbidden (the marriage system); in any case, only a small fraction of men typically engages in plural concurrent unions (the pattern of marital arrangements). In the other society monogamous marriage is enforced, but remarriage is allowed for both men and women (the marriage system); as a result, a large fraction of the population engages in plural nonconcurrent unions (the pattern of marital arrangements). In both societies mating is effectively polygamous: on top of the pattern of marital arrangements, pre- and extramarital sexual relationships are common (the pattern of mating interactions). Finally, reproduction tends to be monogamous, because it is largely confined to sexual interactions within marriage, through the selective use of contraception (the genetic level).

In both cases, knowledge of the marriage system provides limited insight into mating behavior and its reproductive implications. This is why it is problematic to use information on the marriage system to draw inferences about other levels in the framework. Unfortunately, this practice is, to some degree, inevitable. An accurate description of variation in all relevant behaviors would require individual-level genetic data coupled with long-term behavioral observations; these could then be summarized into indices suitable for comparison within and across populations. For obvious practical and ethical reasons, such data are not readily available. As a consequence, studies into the evolution of marriage systems largely rely on typological classifications like the one outlined above, based on the number of concurrent spouses allowed.

Where individual-level data are available (e.g., estimates of reproductive success), these are usually based on self-reports or historical records (e.g., documenting the number of spouses and children), rather than on genetic assessment.

In sum, capturing in a systematic manner the diversity of possible marital and mating arrangements, within and across societies, is riddled with conceptual and empirical difficulties. It will be useful to keep in mind some of the caveats outlined here as we turn to the discussion of marriage system evolution.

Evolutionary Perspectives on Marriage Systems

The 1960s and 1970s saw the development of a conceptual framework for application of evolutionary principles to the study of behavior. This framework was enthusiastically, and in some cases perhaps uncritically, extended to our species. In particular, the framework promised to situate human behavior within a broad cross-specific perspective, while at the same explaining its variation within and across groups. Current evolutionary approaches to human behavior derive

from this framework, in a more or less direct line of descent (see discussion in Laland and Brown, 2011).

Several of the general themes that run through the literature on the evolution of marriage systems developed in this context, grounded in the logic of asymmetry in investment between the sexes (Trivers, 1972). This is the idea that in species with sexual reproduction the sex difference in gamete size leads to divergence in behavioral strategies. By definition, males produce smaller gametes than females. The result of this initial difference in investment is a typical pattern where females care for the offspring, while males seek out additional mates; females are selective in their choice of partners, whereas males are less discerning. This paradigm is currently being revised within biology, to move away from the standard behavioral roles and mating strategies attributed to the two sexes (see discussion in Kokko and Jennions, 2012). The revisions are trickling from biology into anthropology (e.g., Brown et al., 2009; Schacht et al., 2014), but stereotypical assumptions about the behavior of men and women derived from the 'classical' paradigm continue to dominate.

Broadly, studies of the evolution of marriage systems address two sets of questions, relating to variation within and across societies. Where polygamous marriage is allowed, what determines whether an individual marries one or more spouses? And what determines whether the marriage system is monogamous or polygamous in the first place? A third aspect of interest lies at the interface between the two sets of questions, namely the relationship between individual-level outcomes and the rules and norms encoded in the marriage system. For example, does the marriage system emerge through a 'bottom-up' process (e.g., it reflects the prevalent strategy within a group) or through a 'top-down' process (e.g., it reflects the strategy of dominant individuals within the group)? While important, this aspect remains largely unexplored in the evolutionary literature.

Below I outline general themes that run through this literature, with a final word of caution. Although explanations are often phrased in terms of motivations, preferences, choice, strategies, and so on, they do not rest on conscious decision-making by individuals occupied with weighing the fitness outcomes of the different options open to them. Rather, individuals act 'as if' their behavior were driven by such reckoning, possibly mediated by conscious decision-making operating in concert with, or against, the expectation of inclusive fitness maximization. A related issue is that an individual's choice or strategy need not reflect her or his own motivations or preferences: as noted above, it may be the outcome of some degree of 'negotiation' with third parties, such as parents or other kin.

Polygyny as the 'Default' Mating and Marriage System

The central idea derived from the classical paradigm of behavioral biology is that in humans, as in other mammals, polygyny is the 'default' mating system (see recent reviews in Low, 2003, 2007). Men, like males in other species, seek to increase the number of matings, often through intrasexual competition. Women's strategies, like those of females in other species, revolve around intersexual choice, possibly in response to the pattern of resource distribution.

If the marriage system is viewed simply as the cultural amplification of the mating system, a 'baseline' of polygynous mating conveniently explains the prevalence of polygynous marriage systems across societies (82% in the Standard Cross-Cultural Sample; **Figure 1**). The underlying narrative is that men will pursue plural mating as their preferred strategy if individual circumstances allow, and a polygynous marriage system best accommodates this tendency for men to seek polygynous mating whenever possible. The actual pattern of marital arrangements within a polygynous marriage system is the result of variation in individual circumstances.

Two sets of observations are typically used to corroborate this narrative. First, in societies that allow polygynous marriage, polygynously married men tend to be better off, reproductively, than their monogamously married peers. Second, across historical and geographical contexts, dominant men (i.e., those in control of social and/or physical resources, such as political status and material wealth) have directed substantial amounts of effort into the acquisition of multiple mates, in some cases (although not exclusively) through polygynous marriage (Betzig, 1982, 1986). Assuming that dominance enables men to 'get their way,' this is taken to indicate that polygynous mating, possibly through polygynous marriage, is what men ultimately and universally aspire to.

However, this view rests on an overly simplified approach to the relationship between marriage, mating, and reproduction. The underlying assumption is that reproductive success (number of offspring) increases linearly with mating success (number of mates), but this is not necessarily the case (Brown et al., 2009). For example, where males contribute heavily to parental investment, reproductive success increases less than linearly with mating success. The limited evidence available for humans, reviewed in Brown et al. (2009), shows that the relationship between mating and reproductive success varies across populations, for both men and women. This suggests that we should not expect men to always benefit from, and hence seek, polygynous mating.

With reference to the nested framework outlined above, a further difficulty arises from conflation of the marriage and mating levels. Even where men do benefit, reproductively, from polygynous mating, this does not imply that they should always seek polygynous marriage as a result. As we shall see below, in some ecological and social settings polygynous marriage may entail costs for men, which can be avoided through alternative arrangements (Fortunato and Archetti, 2010; Fortunato, 2012). In these contexts, the optimal strategy for men may involve non-polygynous marriage, possibly coupled with polygynous mating (e.g., through extramarital sexual relations).

Finally, recent empirical evidence shows that plural marriage does not necessarily result in long-term reproductive benefits for men. Among the horticultural Pimbwe of Tanzania, there is no evidence of a positive association between number of wives and reproductive success. In this contemporary group polygynous marriage is allowed but uncommon, and plural marriage is typically the result of remarriage following divorce (Borgerhoff Mulder, 2009). In a preindustrial agricultural

Finnish population, number of wives was positively associated with number of children, but it had no effect on number of grandchildren. In this historical group monogamous marriage was enforced, and plural marriage was exclusively the result of remarriage following death of one's spouse (Pettay et al., 2014).

Taken together, these theoretical and empirical insights point to a more nuanced approach to the strategies, motivations, and preferences of men and women than has been generally assumed in the evolutionary literature. As we shall see in the following sections, the view that polygynous marriage best accommodates men's aspiration to mate polygynously has had several repercussions for the study of both polygynous and non-polygynous marriage systems. Somewhat paradoxically perhaps, the strategies, motivations, and preferences of women have received most attention in the context of polygynous marriage – why would a woman marry a married man? Further, non-polygynous systems have typically been approached from the perspective of men, who are viewed as 'relinquishing' polygyny in these systems, possibly driven by peculiarities of the ecological and social environments. As a consequence, explanations have focused on the reproductive implications of non-polygynous marriage systems for men, to demonstrate that relinquishing polygyny 'makes sense,' evolutionarily, from their perspective in these environments. Less attention has been paid to the reproductive implications of non-polygynous marriage systems for women, and to potential conflict and feedback between male and female strategies (Borgerhoff Mulder, 2009; Borgerhoff Mulder and Rauch, 2009).

Polygynous Marriage as Resource Defense Polygyny

Emlen and Oring (1977) introduced a classification of animal mating systems based on the ability of individuals to monopolize mates. One aspect of the classification captures the means through which individuals succeed in this endeavor. For example, in 'female defense polygyny' (also known as 'harem defense polygyny') males control access to mating opportunities directly, by guarding groups of females from potential competitors. By contrast, in 'resource defense polygyny' males exert control indirectly, by monopolizing resources essential to female reproduction (e.g., food or breeding sites).

This classification has found extensive application in the study of marriage system evolution (e.g., Flinn and Low, 1986; Marlowe, 2000). Broadly, the resource defense polygyny model applies where men acquire multiple wives by controlling social resources (e.g., age, political authority) or physical ones (e.g., material wealth). The distinction with the female defense polygyny model is somewhat blurred, however: men's ability to control access to women directly (e.g., in the harems of despotic rulers; Betzig, 1982, 1986) is strongly mediated by their ability to appropriate resources.

Across societies, the degree to which men vary in controlling resources tends to vary with the subsistence system. The resource defense polygyny model applies straightforwardly in non-foraging societies, in which the subsistence system involves the accumulation of physical resources and their transfer across generations, and material wealth may be used directly to acquire a bride (i.e., through bride-wealth, where the groom's family transfers livestock and/or other property to the bride's family). In foraging societies the model may apply where men vary in the degree of control over food-extraction sites (Sellen and Hruschka, 2004) or over social resources (e.g., where age is the basis for access to wives; see discussion in Irons, 1983, pp. 180–185). However, in the majority of these societies there is limited variation across men in the degree of resource control, and the extent of polygynous marriage is therefore limited (e.g., the prerogative of particularly successful hunters). Alexander et al. (1979) labeled this system 'ecologically imposed monogamy' (to distinguish it from 'socially imposed monogamy,' discussed below; note that monogamous marriage is enforced in the latter, but typically not in the former).

The Polygyny Threshold Model, Female Choice, and Male Coercion

Applied to marriage system evolution, the resource defense polygyny model is typically linked to the polygyny threshold model, even though the two do not overlap entirely (see Emlen and Oring, 1977). The polygyny threshold model (Orians, 1969) was developed to explain the occurrence of territorial polygyny in birds, a mating system in which multiple females nest in the territory occupied by their mate (Searcy and Yasukawa, 1989). It applies to situations where males occupy territories of varying quality, and a female's reproductive success increases with the quality of her mate's territory, but it decreases if she has to share resources (e.g., male care, food, nest sites) with other females. Thus, the female incurs a cost by mating with an already-mated male, in the sense that she would be better off mating with the same male but as his only mate.

The polygyny threshold model specifies under what conditions it pays for the female to mate with an already-mated male despite this cost. For example, a female may be better off as the second mate of an already-mated male on a high-quality territory, than as the only mate of an unmated male on a territory of considerably lower quality. In this example, the polygyny threshold is the minimum difference in territory quality between the two males to make the polygynous arrangement advantageous for the female over the monogamous arrangement. According to the model, the occurrence of territorial polygyny in birds indicates that females are sufficiently compensated for the cost of polygynous mating through access to better quality territories (Searcy and Yasukawa, 1989).

Extended to polygynous marriage, this line of reasoning suggests that women may be better off marrying a man who is already married, if he controls sufficiently better resources (in terms of quality and/or quantity) than any of the available unmarried men. A common interpretation, introduced by Chisholm and Burbank (1991), focuses on the reproductive outcomes of women in different marital arrangements within a population. Specifically, if the wives of polygynous husbands do at least as well as the wives of monogamous husbands, this is taken to indicate that polygynous marriage is the result of female choice: the potential costs of sharing resources with co-wives are compensated by access to better resources. If they do

worse, then polygynous marriage is viewed as the result of male coercion: women are 'forced' into polygynous arrangements against their best interest and suffer costs. In this context, male coercion does not involve physical coercion: for example, women may have to tolerate co-wives because they do not have access to other men, or because social norms prevent them from leaving their husbands.

While pervasive in the study of marriage system evolution (e.g., see Lawson and Uggla, 2014, for a recent review), this interpretation rests on a distortion of the framework developed by Searcy and Yasukawa (1989) to explain the occurrence of territorial polygyny in birds. In the original formulation of the framework, under male coercion males are able to physically force females into polygynous arrangements (e.g., through herding or by preventing females from moving off, as occurs in some species of ungulates). By contrast, female choice encompasses a hierarchy of models, some involving reproductive costs for females in polygynous arrangements (e.g., female-biased sex ratios leading to unavailability of unmated males), and others involving no costs (e.g., females recouping the costs of sharing with the male's other mates, through access to better resources). In other words, the polygyny threshold model is only one of a suite of female choice models in the Searcy and Yasukawa (1989) framework. Therefore, it is incorrect to seek to discriminate between male coercion and female choice models based on evidence for or against compensation of the costs of polygynous arrangements to females (an issue discussed already extensively by Searcy and Yasukawa, 1989 and, later, by Borgerhoff Mulder, 1990 in the context of marriage systems).

In short, in the Searcy and Yasukawa (1989) framework costs of polygyny to females are compatible with both male coercion and female choice; in the re-formulation of the framework by Chisholm and Burbank (1991) costs of polygyny to females point exclusively to male coercion. An unfortunate consequence of the conceptual distortion introduced by Chisholm and Burbank (1991) is undue emphasis on male coercion, which is commonly invoked to explain worse outcomes for the wives of polygynous men, compared to the wives of monogamous men. This may partly explain why we have limited understanding of the motivations, or constraints, that lead women into polygynous arrangements, in the face of substantial empirical work focusing on women's outcomes in polygynous marriage systems.

On a related note, the motivations and preferences of men are also poorly understood. This is not surprising, given the emphasis in the evolutionary literature on polygyny as the default mating and marriage system, possibly compounded by a bias in empirical work toward sub-Saharan African societies (Winking et al., 2013). In these societies, polygynous marriage is often associated with prestige, wealth, and status for men; further, multiple wives and their children can be an economic asset, contributing labor to productive activities (Holy, 1996, pp. 63–66). Albeit limited, recent empirical evidence for the forager-horticulturalist Tsimane of Bolivia suggests that similar attitudes are not universal (Winking et al., 2013). In this contemporary population polygynous marriage is allowed but exceedingly rare (and typically sororal, i.e., co-wives are sisters), and both men and women find it less preferable than monogamous marriage. Monogamously married men have no aspiration toward polygyny, and they seem unable to identify any benefits associated with it. Lack of resources is cited as the chief difficulty that arises in polygynous arrangements, followed only distantly by conflict between co-wives.

Monogamous Marriage as Socially Imposed Monogamy

As we saw above, monogamous marriage is enforced in a small but nontrivial fraction of societies (17% in the Standard Cross-Cultural Sample; **Figure 1**). Within an evolutionary framework, explaining the origin of this system against a background of default polygyny presents a challenge. Why would dominant men devise, or allow, a marriage system that removes their prerogative to multiple wives? It seems reasonable to assume that, throughout history, these men have influenced, and to some degree directed, the development of rules and norms encoded in kinship and marriage systems to suit their own interests.

One proposal is that the emergence, maintenance, and later diffusion of such a system across societies were driven by inter-group competition: dominant men had most to gain from success in competition with other groups. In particular, Alexander et al. (1979) proposed that the enforcement of monogamous marriage in stratified societies served to reduce within-group competition among men for access to potential wives, thereby increasing the competitive ability of these societies in between-group conflict. In other words, monogamous marriage emerged as a mechanism of reproductive leveling that served to suppress differences in reproductive success among men. Such a mechanism was a prerequisite for the rise, and persistence, of large nation states. Alexander et al. (1979) termed this system 'socially imposed monogamy' (as distinct from 'ecologically imposed monogamy,' discussed above).

While intuitive, this proposal is not easily reconciled with broad empirical patterns (Fortunato and Archetti, 2010). First, the emergence of monogamous marriage long predates the establishment of large nation states (Herlihy, 1995; Scheidel, 2009). Additionally, the patterned present-day distribution of this marriage system across human societies, suggestive of an association with large nation states, may be the result of an early origin in the history of Indo-European-speaking societies, coupled with diffusion to descendant groups and, later, with processes such as imposition on other groups through conquest (Fortunato et al., 2006; Fortunato, 2008, 2011).

Second, the proposal rests on the key assumption that a monogamous marriage system leads to a substantial reduction in the variance in male reproductive success compared to a polygynous marriage system; in the classical paradigm of behavioral biology, variance in reproductive success underlies competition for access to mates. However, the limited comparative data on male reproductive success available for a sample of societies with monogamous and polygynous marriage systems fail to support this assumption (Fortunato and Archetti, 2010). Consistently, detailed analysis of individual-level data for a preindustrial agricultural Finnish population shows that variance in male reproductive success, and the associated strength of intrasexual competition, can be substantial even in a monogamous marriage system, driven by moderate rates of remarriage following widowerhood (Courtiol et al., 2012).

Finally, recent theoretical revisions of the classical paradigm of behavioral biology (reviewed in Kokko and Jennions, 2012) challenge another key assumption underlying the proposal, namely that the relative 'shortage' of potential wives caused by polygynous marriage inevitably results in increased within-group competition among men. These revisions suggest that male mate competition may be less intense if there is a relative shortage of females available for mating, not more (see discussion in Schacht et al., 2014): why invest effort in competing for an additional mate, if your chances of securing one are low?. In line with the theoretical developments, comparative data on the opportunity for sexual selection (a standardized measure of variance in reproductive success) across a sample of small-scale, nonindustrial societies suggest that the degree of mating competition among men is lower where the sex ratio of the mating pool is more male biased (Schacht et al., 2014).

In sum, if intergroup conflict did indeed play a role in the emergence, maintenance, and later diffusion of monogamous marriage systems, a more nuanced proposal is required that can account for broad empirical patterns, alongside recent theoretical developments.

Monogamous Marriage as 'Monogamous Inheritance'

An alternative proposal explains the emergence of monogamous marriage as a form of 'monogamous inheritance' – effectively a mechanism to channel a man's physical resources to the children of a single wife. In particular, Fortunato and Archetti (2010) investigated whether monogamous marriage can be understood as the outcome of strategic male and female behaviors linked to the allocation of resources to the next generation. Counterintuitively, where this arrangement produces the highest reproductive returns on the investment of resources into future generations, dominant men have most to gain from a monogamous marriage system, because they control the most resources. Further, to the extent that polygynous mating is tolerated alongside monogamous marriage, this proposal does not hinge on reduction in the variance in male reproductive success through monogamous marriage. In this respect, it can better accommodate the distinction between the marriage and mating levels than, for example, the proposal that monogamous marriage is a mechanism of reproductive leveling. At the same time, the theoretical model underlying this proposal (described in Fortunato and Archetti, 2010; Fortunato, 2012) does not consider variation among men in the degree to which they control resources; thus, this factor remains unexplored.

Fortunato and Archetti (2010) identified two conditions that may make monogamous marriage advantageous over alternative arrangements. First, monogamous marriage coupled with unigeniture (i.e., one individual inherits all or most of the resources) can be used to avoid partitioning resources among multiple heirs. For example, in monogamy with primogeniture the wife's first-born child (usually the first-born son) is the designated heir, to the full or partial exclusion of all other children. In polygynous marriage unigeniture typically applies within sets of children by the same mother. For example, in polygyny with primogeniture the first-born son of each wife may be the designated heir among his full siblings. Linking back to the discussion above of the motivations and preferences of women, the polygynous arrangement reflects how each wife (or her kin on her behalf) may require a share of the husband's resources as a condition of marriage. In other words, women may refuse marriage to a married man if inheritance were exclusively by the offspring of the first wife (Fortunato, 2012). As we shall see below, this structural difference in inheritance between monogamous and polygynous arrangements suggests a link to the type of resources transferred, and therefore to the subsistence system.

The second condition that may make monogamous marriage advantageous over alternative arrangements is that women may grant higher fidelity to husbands who marry monogamously over those who marry polygynously. If this is the case, a man's potential reproductive gain from polygynous marriage (i.e., the production of children by multiple wives) may be offset by a loss in terms of reduced paternity, to the point that he may be better off marrying monogamously. In this case, both spouses stand to gain from monogamous marriage: the husband benefits from investing resources 'safely' in those individuals in the next generation who provide the potentially highest reproductive returns (i.e., his wife's children), and the wife benefits from exclusive investment of her husband's resources in her own children.

This proposal is compatible with broad patterns in the history and geographical distribution of marriage systems – namely, why monogamy has prevailed across societies of Europe and Asia practicing intensive agriculture (i.e., plow or irrigation agriculture) and first emerged in these regions, whereas polygyny has prevailed across sub-Saharan African societies with subsistence systems based on extensive agriculture (i.e., horticulture, or hoe agriculture) or pastoralism (Goody, 1976). In intensive agriculture high productivity results in scarcity of land, and division of estates among multiple heirs over the generations leads to plots of land that are too small to sustain a household, effectively depleting the value of the estates. In horticulture scarcity of land is unlikely because productivity is low, and in pastoralism the reproduction of livestock acts as a buffer against scarcity. As a result, productivity is constrained by ownership of land in intensive agriculture, and by availability of labor in horticulture and pastoralism. This difference in the type of resources transferred, itself linked to the subsistence system, may have driven the emergence of monogamous marriage as a mechanism of 'monogamous inheritance' in the agrarian societies of Europe and Asia.

Several predictions can be derived from the proposal, for testing against data in the archaeological, historical, and ethnographic records (Fortunato and Archetti, 2010). For example, we expect to find evidence for an early origin of monogamous marriage, linked to the development of intensive modes of production, and possibly coupled with norms promoting fidelity (e.g., ideologies of honor, or emphasis on female virginity at marriage). This prediction is compatible with the broad historical patterns discussed above with reference to socially imposed monogamy. Further, we expect to see evidence of transitions from a polygynous to a monogamous marriage system (e.g., decreasing rates of polygynous marriage) linked to declines in availability of land, as one of a host of mechanisms

that serve to limit the number of heirs in a given household. Finally, in the ethnographic record we expect to find an association between monogamous marriage and inheritance of resources by a man's wife's offspring (Fortunato, 2009). Note that, for the most part, these predictions relate to the first condition identified by Fortunato and Archetti (2010). Predictions relating to the second condition may be harder to validate, given the difficulties involved in obtaining reliable comparative data on paternity rates, for both (pre-)historical and contemporary populations.

Polyandrous Marriage as a Response to Environmental Challenges

As we saw above, only 1% of societies in the Standard Cross-Cultural Sample are coded as polyandrous (**Figure 1**). This is likely an underestimate, however, reflecting a bias in anthropology toward a narrowly focused set of classic ethnographic descriptions (Starkweather and Hames, 2012). With one exception (the historical population of the Marquesas Islands in the South Pacific; see discussion in Harrell, 1997, pp. 267–271), these descriptions pertain to societies in the Himalayan regions of India, Nepal, and Tibet (discussed below). Starkweather and Hames (2012) recently identified several additional cases in the ethnographic record, noting that they have received limited attention in the study of marriage system evolution.

According to Starkweather and Hames (2012), two key differences between 'classical' and 'nonclassical' polyandrous marriage systems are that the incidence of polyandrous unions tends to be considerably higher in the former, and that polygyny alongside polyandry is found in the former but not in the latter. Recall that terms that more accurately describe the co-occurrence of the two forms of plural marriage ('polyandrogyny' and 'polygynandry') are used rarely and inconsistently in anthropology. Below I use the term 'polyandrogyny' for systems where both sexes vary in number of spouses, but women are more variable than men (Shuster and Wade, 2003, p. 161).

Our understanding of marriage systems where plural concurrent husbands are allowed is rather limited, perhaps as a result of these and other biases (e.g., the near-exclusive focus on outcomes for men). Broadly, this phenomenon is viewed as a response to peculiar social and/or ecological conditions, such as an unbalanced sex ratio leading to severe scarcity of marriageable men or a circumscribed, harsh ecology requiring the pooling of male labor (see reviews in Levine and Silk, 1997; Starkweather and Hames, 2012).

For example, a particular combination of ecological conditions may explain why some societies in the Himalayan regions of India, Nepal, and Tibet resort to fraternal polyandrogynous marriage, where one set of brothers is married to a single wife (see review and discussion in Barrett et al., 2002, pp. 224–233). As in other intensive agricultural societies of Europe and Asia, the risk of land scarcity is high (in this case through low carrying capacity rather than through increased productivity and subsequent population growth). At the same time, the land requires high labor input and yields low productivity, as in the extensive agricultural societies of sub-Saharan Africa (Fortunato, 2009, p. 38). In this ecological context, fraternal polyandrogynous marriage may serve two functions (Goody, 1976, 1990). The first is to limit the number of heirs to an estate: the 'monomarital principle' (Goldstein, 1971) limits the number of wives whose children have claims to the estate. The second function is to concentrate the labor of a set of brothers into the same household, ensuring an adequate workforce against the low productivity of the land.

From an evolutionary perspective, if this arrangement is indeed a response to harsh ecological conditions, a man in a polyandrous or polyandrogynous union is expected to do better, reproductively, than his peers in monogamous or polygynous unions (taking into account his own reproductive outcomes and those of his brothers). However, tests of this prediction are inconclusive, marred by practical difficulties such as the relatively small numbers of brothers at a given 'rank' within a household and uncertainty in the assignment of paternity among them (see review in Barrett et al., 2002, pp. 224–233). Conceptually, a further difficulty arises from interpretation of the data in an evolutionary context. If a key function of polyandrous/polyandrogynous arrangements is to limit the number of heirs, in the interest of long-term lineage survival (i.e., by keeping the family farm intact), the focus on the reproductive outcomes of individual men is misplaced. Analysis should focus on the reproductive implications for men (and women) as parents, rather than on those for men as husbands (Barrett et al., 2002, p. 229). Further insight may derive from research into the factors associated with the dissolution of polyandrous/polyandrogynous households when outside options for men become available, such as employment opportunities not linked to the family farm (e.g., Levine and Silk, 1997; Haddix, 2001).

An additional open question relates to broader patterns of variation across societies in the Himalayan region faced with what appear to be similar ecological challenges: not all groups resort to plural concurrent marriage for women or to the same set of inheritance norms. This has led to the suggestion that historical contingency may have played a greater role than ecological factors in shaping the observed distribution of marriage systems in the region (Berreman, 1978). In sum, of all the marriage systems those involving plural concurrent husbands are the least well understood.

Concluding Remarks

This article has introduced key concepts and general themes in the study of marriage system evolution. The overview has revealed some broad trends. Marriage systems were initially viewed as the cultural 'analog' of mating systems; as a result, early work focused on their ecological correlates (e.g., amount of rainfall or parasite load), failing however to uncover clear patterns (see reviews in Low, 2003, 2007). The realization that marriage may have more to do with the transfer of social and/or physical resources across generations than with mating and the production of children is shifting the focus toward the interplay of the marriage system with a broader range of ecological and social factors.

At the outset, this body of work was firmly grounded in the classical paradigm of behavioral biology, with its emphasis on asymmetries in investment between the sexes. Recent revisions of the paradigm are slowly being incorporated into evolutionary

approaches to marriage systems, but classical views continue to dominate (e.g., a bias toward the reproductive outcomes for men; Borgerhoff Mulder, 2009). These revisions suggest a more nuanced approach to conflict and to feedback between male and female strategies, and their coevolution with environmental factors.

Abstract

Founder of the 'Cambridge School of Economics' and mentor of John Maynard Keynes, Marshall was one of the leading economists of his era. After studying mathematics at Cambridge University in the UK he taught economics at Cambridge, Bristol, and Oxford before returning to Cambridge as professor in 1885, retiring in 1908. His influential *Principles of Economics* (1890) set out his main contributions to the theories of value and distribution. Especially associated with his name are the concepts of partial equilibrium analysis, consumer surplus, short-period versus long-period analysis, external versus internal scale economies, derived demand, and demand elasticity, all still in general use. He remained in the deductive tradition of the British classical school, seeking to improve rather than overthrow it, emphasizing the need to use deduction cautiously, with close attention to the facts of the situation being analyzed. Influenced by evolutionary ideas he stressed the importance of changes in the human factor. He published too late to be an originator of the neoclassical or marginalist revolution commencing in the early 1870s but was prominent in extending marginalism to distribution theory. Two further works, *Industry and Trade* (1919) and *Money Credit and Commerce* (1923) came too late to have much impact on economic thought.

Alfred Marshall, one of the leading economists of his era, was the progenitor of the 'Cambridge School of Economics,' which rose to world prominence in the interwar period. His *Principles of Economics* (1890) was a seminal work in the development of economic thought and introduced tools still prominent in the practice of applied economics.

The Man

Marshall was born in Bermondsey, a London suburb, on 26 July 1842, second son of William Marshall, a clerk at the Bank of England, and his wife Rebecca, née Oliver. He grew up in London, attending the venerable Merchant Taylors' School where he revealed considerable intellectual power and an aptitude for mathematics. Entering Cambridge University, he pursued the prestigious mathematical tripos, graduating in 1865 in the exalted position of 'second wrangler' – a result guaranteeing election as a fellow of his college, St. John's. His interests soon turned from mathematics to questions of human and social existence, and in 1868 he became a lecturer in moral sciences at St. John's. The moral science tripos covered philosophy, logic, and political economy. He lectured on political economy more from necessity than choice. But, perceiving that human and social advance would be possible only if economic constraints became less oppressive he soon settled on the subject as the focus for his life's work and was to be influential in renaming it 'economics.'

He rapidly became Cambridge's dominant teacher of the subject. While publishing little, his early manuscripts (reproduced in Whitaker, 1975) demonstrate that by the early 1870s he had developed many of the distinctive theoretical ideas later associated with his name. He also strove to attain a realistic grasp of the economic world both past and present. Reluctant to produce a theoretical monograph devoid of concrete application, he commenced a volume on international trade questions, visiting North America in the summer of 1875 for fieldwork. Although largely completed and accepted for publication, the project was abandoned in the late 1870s. But in 1879 H. Sidgwick privately printed two of its appendices for circulation in Cambridge and a few copies reached economists elsewhere. Known as *The Pure Theory of Foreign Trade* and *The Pure Theory of Domestic Values* these remarkable pieces were the high watermark of Marshall's achievement in pure economic theory but were not widely known or accessible in his lifetime. (Whitaker, 1975 provides the fullest version together with surviving portions of the text of the abandoned volume.)

In 1876 Marshall became engaged to Mary Paley, a Newnham lecturer, who had attended his early lectures for women and informally sat the 1874 moral sciences tripos examination. The two were married on 17 August 1877. Marriage required Marshall to resign his fellowship and he found a new livelihood as first principal of University College, Bristol. Here both Marshall and his wife taught economics. Meanwhile, he had taken a hand in the writing of a primer for extension classes, started by Mary Paley before their engagement. It increasingly became his book and appeared under their joint names as *The Economics of Industry* (1879). While ill-judged for its intended audience, it contained much novel material, including a theory of income distribution on marginal productivity lines. Its original features helped establish Marshall's reputation amongst economists, especially abroad.

The fledgling Bristol college lacked financial support, and the tasks of administration and fund raising proved uncongenial to Marshall, anxious as he was to develop and publish his own ideas. Ill health, diagnosed as kidney stones, constrained him further and he resigned with relief in July 1881, spending much of the next year traveling in Europe, with an extended stay in Palermo where composition of his *Principles* began.

The following academic year was again spent in Bristol, where the pair taught economics, after which Marshall – who had become a protégé of B. Jowett, the eminent Master of Balliol – moved to Balliol College, Oxford, as lecturer to the probationers for the Indian Civil Service. The move to Oxford had been viewed as permanent with good prospects for elevation, but the sudden death of H. Fawcett – professor of political

economy at Cambridge since 1863 – offered the possibility for a return to Cambridge in an assured, independent, and well-paid position. Marshall had already come to be recognized, after the 1882 death of W. S. Jevons, as the UK's leading economist and he took up the Cambridge chair in early 1885, retaining it until 1908 when he voluntarily retired at age 65.

Fawcett had carried the professorship lightly, combining it with an active political career. But Cambridge was changing rapidly and expanding its commitment to modern subjects. With the lapsing of celibacy requirements, new-model professors and lecturers devoted themselves to the tasks of teaching and advancing knowledge. Marshall gave much effort over the years to lecturing and advising students, urging the more promising to follow the high calling of the economist. Despite frequent disappointments, he did manage to inspire a number of students who were to be prominent in the development of British economics, among whom A. C. Pigou and J. M. Keynes were conspicuous. From the outset, Marshall strove as professor to expand Cambridge's scope for economic teaching, but with only modest success. He eventually secured in 1903 a new specialized tripos in economics and politics, but few resources were provided for it. The new degree only became firmly established after his retirement, but the seed he planted reached full flowering in the 'Cambridge School' of the interwar period.

The 1880s saw the most copious flow of occasional publications by Marshall as well as his important evidence to the Gold and Silver Commission of 1888–89. (Most of his occasional writings are collected in Pigou 1925, which includes a virtually complete, bibliography. Materials concerning his participation in government enquiries are collected in Keynes, 1926 and Groenewegen, 1996.) *Principles*, on which he had been working since 1881, at last appeared to widespread acclaim in 1890. It was a success not only among academic peers at home and abroad but also with an educated public, gratified by its undogmatic and conciliatory tone and its evident concern for human well-being. Marshall's intention had been to follow *Principles* – initially subtitled Volume I – with a companion volume devoted to the applied branches of economics, an idea eventually abandoned as unworkable after intermittent efforts over the next decade or more. Meanwhile considerable effort went into revising *Principles*, which was to go through eight editions in his lifetime, the last being in 1920. (Guillebaud, 1961 reprints the last edition with variant passages from earlier editions.) The copious rewritings and frequent rearrangements did not mark significant changes in Marshall's views and tended to impair the work's vigor and overall clarity. A condensation of *Principles* appeared as *Elements of Economics of Industry* in 1892, replacing the earlier work written with his wife, which he had come to dislike intensely. (Like the earlier work it included a treatment of trades unions omitted from *Principles*.)

Marshall's next book, *Industry and Trade*, only appeared in 1919, long after his retirement. It was started in 1904 in the aftermath of the UK's intense controversy over the desirability of maintaining free trade and was initially conceived as a short topical book on the issue of the day. But it soon developed into a more ambitious attempt to study the interrelationships between distinctive national conditions of industry and patterns of international trade. A motivating force was Marshall's deep concern for the UK's seemingly parlous economic future. Progress on the book was slow and delayed by war. The volume appearing in 1919 was only a fragment of the complete scheme with a vague promise, never fulfilled, of a continuation. An applied work, rich in contemporary detail but lacking in focus, it had a respectful reception but little impact. It nevertheless remains a remarkable if neglected work, displaying full vigor and wisdom of mind and much acumen about economic arrangements.

Marshall's last book, *Money Credit and Commerce*, was assembled with unprecedented speed, appearing in 1923. It brought together material, often written decades earlier, on money, the business cycle, and international trade and payments. Here the 50-year-old graphical analysis of *The Pure Theory of Foreign Trade* was published at last. Unfortunately, waning powers precluded a new synthesis, but the book has incidental merits.

Marshall died on 13 July 1924 at Balliol Croft, his Cambridge home since 1886. His wife was to outlive him by almost 20 years. She taught economics at Newnham for many years after their return to Cambridge, but any intellectual ambitions of her own were subordinated to the task of relieving her husband of everyday vexations.

Balliol Croft was the center about which Marshall's life had revolved after 1886. Under pleas of weak health he only left reluctantly as professional or social duties required. However, summers were normally spent in lodgings away from Cambridge – usually on the south coast of England or in the Tyrol – where he could write free of everyday distractions. But he was not a recluse. Balliol Croft saw many visitors and there were frequent 'at homes' for dispensing advice to students. While not relishing academic dispute, he strove to keep in touch with the real world by quizzing all in active life who came in his way: businessmen, trades unionists, social workers, and so on. Factory visits and inspections of working class life were also valued.

Marshall's was a complex and contradictory personality, which it is now difficult to assess. Prone to fuss over details, and sometimes lacking common sense, he was nevertheless inspirational, especially to the young, in his commitment to the advancement of his subject and his intense conviction of its importance for society's well-being. He had remarkable conversational powers and an impressive ability to speak extempore. Above all, his subtle and wide-ranging mind saw complexities that eluded others and made it impossible for him to communicate his thought in a cut-and-dried way. His economic writings both benefit and suffer from this characteristic. They benefit from a breadth of vision and a richness of unexpected and thought-provoking insights. They suffer from a lack of full coherence and clear articulation, making it frustratingly difficult to grasp and describe his thought comprehensively. Marshall himself struggled incessantly with the daunting task of transferring his thought to the printed page, a task further complicated by an undue sensitivity to criticism and an incessant urge to rewrite already adequate texts.

The Background to Marshall's Economics

British economics was at a critical juncture when Marshall came to it around 1870. The ideas of the classical economists,

especially J. S. Mill whose *Principles* (1848) was still dominant, seemed out of tune with the needs and spirit of the age. The publication of Jevons's *Theory* (1871) was a notable harbinger of the coming transformation from classical to neoclassical economics, which – while maintaining the deductive tradition of the classicals – was to emphasize the role of demand, the assumption of optimizing behavior, and the use of mathematical formalization. The British deductive tradition itself was coming under increasing attack from historically minded economists, especially in Germany, who sought to rely on induction and case studies as the best means of augmenting economic knowledge. More generally, Darwinian ideas on evolution were challenging traditional certainties, while there was increasing social concern over the growing political power of the working classes and the hard plight of the poorest.

Marshall was strongly influenced by this intellectual milieu. His initial economic studies centered on Mill's rendition of classical theory but his mathematical background, allied with his early discovery of the neglected work of A. A. Cournot (1838), pushed him towards a mathematical – mainly geometrical – mode of argument. In contrast to Jevons he saw no need to overthrow the inherited classical system and only sought to close its gaps while preserving its important insights. He remained firmly in the British deductive tradition but mistrusted extended deductions based on oversimplified formalizations. He sought to guide deduction by maintaining close contact with observation and history and by allowing fully for disturbing causes. Although somewhat sympathetic to the aims of the historical economists, he emphasized that observation without the aid of a coherent analytical framework or 'organon' could yield little useful knowledge. Influenced especially by the views of Herbert Spencer, he placed great emphasis on the way human character was formed by the experiences of home, workplace, and leisure activities. This opened the possibility of gradual change in human character by the intergenerational transfer of acquired traits, a process more Lamarckian than Darwinian. On the other hand, he strongly resisted the idea that human nature could be transformed by drastic social changes. He attached great importance to the gradual improvement of character and abilities, especially in the lower ranks of society. His ideals here were perhaps parochially reflective of the middle class mores of his era but they were heartfelt. Economic progress was to him not an end in itself but a means to the improvement of mankind. Faced by a choice between the two he would perhaps have chosen human over economic gains, but he fortunately saw them as complementing and reinforcing each other. He declined to base economics on an artificial 'economic man' and sought to deal with human nature in the round, giving recognition to the constraints of duty and the striving for recognition among professional peers. While conceding that the economist as such has no special standing as adviser on normative matters, he did not let this restrain him and was indeed something of a preacher.

Theoretical Contributions

Marshall's mature contributions to the theory of value and distribution build upon his earlier treatments in *The Pure Theory of Domestic Values* (1879) and *The Economics of Industry* (1879 jointly with M. P. Marshall) and are to be found in books 3, 5, and 6 of all editions of *Principles* after the first.

Book 3 of *Principles* deals with consumers' demand. The focus is on the quantity of a particular good demanded by a consumer at a given price and the 'consumer's surplus' consequently obtained. This surplus arises from the fact that a consumer's demand price for an additional unit falls as successive units are acquired and equals purchase price only for the final or marginal unit bought. Marshall's derivation of an individual's demand curve, contingent on tastes, income, and other prices, and based on the assumption of diminishing marginal utility, provided a simple if limited foundation for a downward sloping market demand curve for a good, relating its price to aggregate quantity demanded. It remains a staple of elementary pedagogy, as does his related concept of demand elasticity. The consumer's surplus notion seems to have been an independent rediscovery of a neglected idea developed by the French engineer J. Dupuit in the 1840s. Marshall was well aware of the limitations of welfare arguments based on this individual-specific monetary measure of benefit. The individual's marginal utility of money must remain constant, and interpersonal aggregation requires strong assumptions. Nevertheless, the concept continues to be widely used in applied economics.

Book 5 of *Principles* brings together market demand and supply for a commodity, taking for granted the broader economic context – an approach known as 'partial equilibrium' analysis which is closely associated with Marshall although hardly original to him. The treatment of supply is restricted to the extreme cases of monopoly and thoroughgoing competition, although the latter is often more akin to modern theory's imperfect competition than to its perfect competition. (*Industry and Trade* (1919) was to probe interestingly into the intermediate case of trusts, cartels, and 'conditional monopolies' always threatened by potential entrants.) The treatment of monopoly does not advance significantly beyond Cournot, apart from a remarkable brief treatment of socially optimal pricing by a publicly owned monopoly. The treatment of supply in the competitive case is more notable. There are two distinct lines of innovation. 'Period analysis' recognizes that quantities of some productive inputs may not be alterable in a limited time so that the industry's supply conditions become contingent upon the length of the period to which the analysis is meant to apply. Moreover, payments to any type of input will be determined by the cost of securing its use to the industry only if there is enough time to vary freely the quantity employed. Otherwise, payment to such inputs has the character of a rent – termed a 'quasi rent' – determined by the product's price rather than helping to determine this price as a necessary element in production cost.

The other notable feature is the explicit consideration of scale economies in production. External economies are due to the growth of the size of the industry as a whole rather than the sizes of its constituent firms. They reflect osmosis of worker skills, increased opportunities for specialization, and so on. Although somewhat elusive, the idea of such economies remains significant in modern economics. Internal economies are due to a growth in firm size that permits more efficient large-scale production methods to be utilized. While often plausible, a persistent ability of larger firms to undercut smaller firms threatens the viability of atomistic competition.

Marshall's solution, implied in his 'representative firm' concept, was to combine market and organizational restrictions on rapid firm expansion with a life cycle for the firm due to a waning of entrepreneurial drive on the part of the founder's successors. Such an argument applies more to the Victorian family firm than to the modern joint stock company, which was to take the limelight only in *Industry and Trade* (1919). The modern 'representative agent' concept owes little to Marshall beyond the name.

Scale economies under competition permit the supply price at which any quantity of a good is supplied to the market to fall with quantity, just as the corresponding demand price does. This admits the possibility that there may be more than one market-equilibrium quantity at which supply price equals demand price. The so-called Marshallian adjustment process through which market equilibrium is attained is very much in the classical tradition deriving from A. Smith. Price adjusts to clear the market of whatever quantity is made available, thus settling at the demand price for that quantity. Then the quantity supplied increases (decreases) as the supply price at the initial quantity is below (above) this market price, so that super-normal (infra-normal) profits are being made. An equilibrium quantity is unstable if there is divergence from it.

The possibility that there may be more than one market equilibrium that is stable for small perturbations is sufficient to disprove a claim that a competitive equilibrium must maximize social welfare. Marshall was clear that the most that could be claimed was what came to be called Pareto optimality. But he showed in a remarkable argument that even this might not be true, demonstrating that a social gain may be obtained by taxing an industry whose supply price rises with quantity in order to subsidize an industry having falling supply price. His analysis of this and other welfare issues drew heavily on the consumer-surplus concept and foreshadowed much in the 'new welfare economics' emerging in the 1930s.

Partial equilibrium analysis was extended in book 5 of *Principles* to cover a group of closely interrelated markets, as exemplified by a set of goods jointly demanded or supplied. More general is the interaction between the markets for an output and its several inputs. Here Marshall introduced the idea of derived demand – the demand for inputs being derived from the demand for the output they jointly produce – fruitfully characterizing the determinants of the elasticity of derived demand for any one input. Even if the number of goods involved is large, the analysis of such multi-market cases remains partial equilibrium in nature since an economy-wide setting that is little influenced by what happens in the markets analyzed is still tacitly assumed.

Only in *Principles* book 6 did Marshall turn to a consideration of the entire economy and its complex mutual interactions between value, production, and income distribution. His approach was macroeconomic, centering on the concept of the 'national dividend' or national income. This was seen as the combined product of the various factors of production, each unit of which claimed a share equal to its marginal product. Increased quantity of a homogenous factor would lower its marginal product but raise the national dividend, while the absolute or relative shares accruing to the entire factor could rise or fall.

The 'law of substitution' in production and consumption (essentially cost minimization and utility maximization), together with the equality of prices to all-inclusive costs required for competitive equilibrium, ultimately settle equilibrium prices for all goods and factors: also the quantity of each good produced, together with the quantities of the various factors used to produce it. None of this is described with any formality. It remains more a general vision than a precise theoretical statement that might rival the general-equilibrium theory of L. Walras. What book 6 effectively does, however, is to integrate a neoclassical marginal-productivity approach to the demand for factors of production with a classical approach to their supply (extensively developed in *Principles* book 4). This results in a real cost explanation of factor price determination in the long period. If factor supplies were permanently fixed, then factor prices would be determined wholly by the derived demand for their services, and the cost of any particular use would only be the opportunity cost of potential earnings in the best alternative use. But if, as Marshall supposes, continual replacement flows are needed just to maintain factor supplies then factor prices must exactly remunerate the real cost of eliciting these replacement supplies while still satisfying the derived-demand or marginal-productivity condition.

For Marshall, capital, labor of all kinds including managerial labor, and even business organization when firms have finite lives, all require replacement flows to maintain their levels. The case of labor is particularly complicated in the long period. Parents often make decisions for their children about occupation and acquisition of human capital, while the expected return to investment in human capital provides inadequate surety for borrowing to undertake it, being both uncertain and incapable of ownership transfer. A further complication is the 'economy of high wages' which results when increased wages improve worker efficiency by boosting physical or mental well-being, a possibility to which Marshall attached considerable importance. Indeed, his treatment of labor markets is one of the most valuable features of *Principles* book 6.

Apart from those embodied in *Principles*, Marshall's theoretical contributions are limited. His foreign trade analysis (1879) with its ingenious offer curves was indeed an important advance on Mill's treatment, but highly restricted circulation limited its impact. On money, he had a masterly grasp of British monetary tradition but added little that was novel. His most significant innovation was to replace the velocity of circulation with a demand for money function, a change which already appeared in an early manuscript and was to remain influential in the Cambridge monetary tradition leading up to Keynes's *General Theory* (1936).

Policy Views

Marshall was a proponent of economic freedom and free trade but not a doctrinaire one or an advocate of extreme *laissez faire*. He saw government as having important functions in regulating market forces and remedying or alleviating the problems they produced. Redistributive taxation was acceptable, even desirable, if it did not threaten the security of property or incentives to effort. For the well-to-do striving to keep up with their neighbors, or for professionals seeking the acclaim of their peers, Marshall saw absolute incomes as largely symbolic and felt that taxation which preserved income relativities in the middle and upper

classes would not have serious disincentive effects on effort, saving, or risk-taking. Town planning and provision of recreational facilities were needed for the well-being of the urban working classes, the young especially, while a government safety net was needed for those in abject poverty, although private charity could be more discriminating in the incentives it offered and in distinguishing the deserving from the undeserving. To 'administrative socialism' – proposals that government take over the active management of most industries – he objected violently, however. He foresaw that it would result in widespread bureaucratic lethargy and an undermining of the freedom to experiment and innovate essential to economic progress and society's future well-being. Increasingly he came to feel that the UK's future prosperity must rest on the chivalric competition of those in control of private business, freed from intrusive government regulation and from enervating protection against foreign competition. He took relatively lightly the possibility that cartels, combines and monopolies might come to dominate, viewing them as continually undermined by economic change. His early hopes that involvement in trades unions and cooperative societies would induce among workers an appreciation of and sympathy for the complexities of business management waned and he came to fear organized labor as an ossifying factor second only to the heavy hand of government and itself a distinct threat to the UK's international competitiveness. But, after the sobering experience of war and its expanded government control of the economy, *Industry and Trade* (1919) was to place more reliance on conscious industry-wide collaboration between management, labor, and government.

Education had a vital role in raising the working classes by improving abilities, skills, and ambitions, as workers, parents, or citizens. Schools and technical colleges, provided or sponsored by the government, were crucial, but Marshall stressed that much practical education occurred in the workplace: also in the home, where the duties of mothers and daughters were urged and extolled.

On monetary arrangements, Marshall's preference was for a managed paper currency operating within an international gold-exchange standard. His proposal in the 1880s for 'symmetalism' – use of a fixed-quantity combination of gold and silver as the monetary base – was only offered as a superior alternative to the clamor of the time for fixed-price-ratio bimetallism. His preferred goal for monetary policy was to maintain fixity of nominal input prices rather than output prices. Productivity increase would thus yield declining output prices. To palliate the effects of unforeseen price-level changes he proposed voluntary indexation of private contracts by means of a price index or 'tabular standard' published by the government.

Place in Economic Thought

Marshall can claim some subjective, but limited objective, originality as a contributor to the opening round of the so-called neoclassical revolution, initiated in the 1870s by the writings of Jevons, Walras, and C. Menger, although quite fully anticipated in the then largely forgotten writings of Cournot, Dupuit, H. H. Gossen, and others. He has stronger claims to have been an important contributor to the second round, culminating only in the 1890s, which extended marginalism from value to distribution by means of the marginal-productivity concept. Here, he claimed to have been influenced early on by the work of J. H. von Thunen, although the evidence for this is meager. But the lasting impact of Marshall arises less from transforming ideas than from the provision of serviceable tools which still remain in everyday use: partial-equilibrium analysis, consumer's surplus, demand elasticity, derived demand, long-period versus short- period analysis, and so on. These ideas remain prominent in applied work and pedagogy even if they no longer feature prominently at the frontiers of theoretical research. They perhaps serve as mute testimony in defense of Marshall's distrust of extended abstract theorizing and his preference for being roughly relevant rather than precisely and elegantly irrelevant.

But Marshall's impact on the development of economics came as much, if not more, from his influence on his students and his role in the professionalization, or perhaps better academicization, of economics in the UK as from the impact of his ideas. His *Principles* (1890) was prominent for 30 years or more in the training of economists in English speaking countries, while his students took over many of the new economic posts arising in the UK as higher education expanded, or else became prominent in government service. His struggles to establish economics more firmly in Cambridge bore later fruit in the influential 'Cambridge School,' although his intellectual hold on it had greatly weakened by the 1930s. Anxious that economists should present a public facade of unity and cumulative progress, he was led to present neoclassical ideas as more evolutionary than revolutionary and to take a conciliatory tone in methodological disputes, especially in dealing with the claims of the German historical school. While not an active promoter of, or participant in, professional organizations of economists, he placed his ecumenical imprint on the British Economic Association, founded in 1890 and subsequently renamed the Royal Economic Society.

Equilibrium analysis based on fixed conditions and fixed human response-patterns was only a first step for Marshall, the beginning rather than the end of economic knowledge. His evolutionist leanings led him to decry such analysis as merely mechanical and to look for approaches that were more biological in nature and which recognized the mutability and path-dependence of human character and institutions. His interest in such approaches was not to be much developed and remains somewhat enigmatic. Of particular interest in this connection is his analysis of the intertwined emergence of free enterprise and economic thought moved from *Principles* book 1 to *Principles* Appendices A and B after edition 4. Modern mainstream economics, although considerably indebted to Marshall, has hardly adopted his broader agenda, which indeed seems to have had little influence on the work of his students. Today's economic heterodoxy thus can often find both target and support in Marshall's work.

Further Reading

Keynes's biographical memoir (in Pigou, 1925) is not to be missed, and there is now a scholarly full-scale biography (Groenewegen, 1995) and a comprehensive edition of

correspondence and related documents (Whitaker, 1996). There is no satisfactory monograph on Marshall's economic thought but Tullberg (1990) and Whitaker (1990) provide assessments by various authors on the centenary of *Principles*. Wood (1982, 1996) provides a convenient but undiscriminating reprint in eight volumes of pertinent articles from academic journals.

Abstract

T.H. Marshall's name is ubiquitous in citizenship scholarship. This recount of T.H. Marshall's accomplishments moves from a brief acknowledgment of him as an academic and citizen to his sociology of citizenship and its students and critics, and ends with a commentary on citizenship today and Marshall's influence on its theory. It is the tension between heightened expectations about the transforming capacity of citizenship and continuing inequalities in society that makes Marshall's work still relevant at the beginning of the twenty-first century.

As one of the most prominent British social and political theorists in the twentieth century, T.H. Marshall's work has significantly shaped the literature on citizenship. The never fading relevance of T.H. Marshall's work is evident in the vast literature on citizenship, written in the last three decades, either in response to Marshall's own writings or as a critique of his work. With each reimagination of citizenship, we are left with no choice but return to Marshall's original formulations.

This recount of T.H. Marshall's accomplishments moves from a brief acknowledgment of him as an academic and citizen to his sociology of citizenship and its students and critics, and ends with a commentary on citizenship today and Marshall's influence on its theory.

T.H. Marshall as an Academic and Citizen

If not disrupted by an imprisonment in a German civilian internment camp during World War I, T.H. Marshall would have followed the familiar path of English upper-middle class career-pattern – from boarding school to Oxbridge, with a likely career in the Foreign Service. Instead, equipped with a stronger 'social awareness and commitment,' Marshall opted out for sociology at the London School of Economics (LSE), where he had a distinctive career and provided a 'distinguished role model for aspirant sociologists' (Halsey, 1996; Smith, 1996). Marshall taught comparative social institutions at the LSE, with a firm interest in sociological explanations of social change and sociology's potential in creating that social change (Lockwood, 1974). It is this commitment to social issues and change, both as an academic and as a public intellectual, David Lockwood argued, made Marshall's work a par with those classical texts that paved the way for modern sociology. This commitment is evident in Marshall's combination of academic life with public service. He worked in the Foreign Office Research Department during World War II; served as educational adviser to the British High Commissioner in Germany from 1949 to 1950; and took the Directorship of Social Sciences in UNESCO when he retired from the LSE in 1956.

To accentuate Marshall's lifelong identification with sociology is no overstatement. Contemplating on his 4 years of imprisonment in Germany in an autobiographical piece, he recalls that in most of his letters to home he wrote evidence of 'a growing sociological curiosity about what was happening' to him and around. Marshall goes on to say that "if only [he] had been a sociologist then, what an opportunity this would have given [him] to study, by participant observation and any other survey method, the emergence of a structured society from a miscellaneous individuals by chance in a confined space, and its subsequent fortunes" (Marshall, 1973: 89). It is as if the sociologist in him made intelligible, and bearable, 'the world around' him and 'the remarkable social experiment' he had endured for 4 years. Marshall left the prison 'deeply affected' by the experience and with a strong resolve to start an academic career.

As a sociologist, Marshall contributed significantly to the study of social stratification and social policy. His seminal piece on citizenship, *Citizenship and social class*, established the many themes that have occupied our scholarly and intellectual agendas since then and for years to come, never diminishing in their import and urgency (the essay was first given as a lecture in 1949 at the University of Cambridge and then published in 1950). His collected essays *Sociology at the Crossroads* (first published in 1963; the American edition with a foreword by S.M. Lipset appeared under the title *Class, citizenship and social development* in 1964) and his text *Social policy* (1965) are still required readings in many countries and many languages. In the 1990s, Marshall's ideas have come to fore, not only in the excess academic literature on citizenship, but also in politics as A.H. Halsey (1996) asserts, with the transformation of the social democratic welfare state away from its 'socialistic' strands to a position of 'welfare capitalism.'

His was half-a-century of remarkable achievement in writing on and advocating for just citizenship and policy (Smith, 1996). In this lies his resonance in the advent of an age anticipating tumultuous shifts in the order of citizenship as we know it.

T.H. Marshall's Sociology of Citizenship

Marshall's was an evolutionary sociology grounded in economic history. *Citizenship and social class* combines elemental aspects of both of these disciplines effectively. His interest in equalities and inequalities, and thus, citizenship was shaped through his study of postfeudal England as a PhD student in Cambridge, as well as his day-to-day experiences with 'class' during his interment in Germany and during his brief encounter with politics as a Labor candidate in 1922.

Marshall's work on citizenship is an attempt at 'grand sociology.' It attempts to trace a 'developmental process' – the process of the development of citizenship rights. Marshall did this based on the reading of the British case, but nevertheless with the aim of chartering a more general map for the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61087-5

progressive development of rights. Each citizenship right built upon each other and labored the next one. The development of civil, political, and social rights not only corresponded to the eighteenth, nineteenth, and twentieth centuries in a sequential order, but also each one was the necessary condition for the other. Of this account of advancement of citizenship, Anthony Rees writes: "… [In the 1950s] Marshall almost single-handedly revived the notion of citizenship, and disseminated a particular view of it so successfully that it came to be seen (at least in England) as the only possible account" (1996: 3).

Marshall's interest in explaining citizenship rights has a purpose. It stems from his conceptual and political concerns for class and class inequalities. Marshall concedes that citizenship rights, in their earlier stages, were necessary for the flourish and maintenance of capitalism, a system of inequality in itself. The civil rights of individuals, particularly the right 'to own property and to conclude valid contracts,' were the necessary foundations for a market economy. But it is the inequalities generated by the capitalist market that the subsequent citizenship rights were contrived to alleviate. Here enter social rights as corrective and as a unifying force.

For Marshall, social rights constitute the 'inevitable capstone' of citizenship development. Substantive social entitlements and rights guaranteed by the welfare state should prevent social and economic exclusions that the earlier provisions of civil and political rights could not. This redefinition of citizenship, from a minimum of legal and political rights to a substantive body of social entitlements, is what made Marshall's lasting intellectual contribution (Somers, 1993; Rees, 1996).

And it is this conception of modern citizenship that has been a major inspiration and challenge to those whose intellectual concerns lie in democracy, equality, and social conflict. On both sides of the Atlantic, the difficult relationship between citizenship and social class dominated the scholarly agendas of 1950s and 1960s (Reinhard Bendix, Ralph Dahrendorf, A.H. Halsey, Seymour Martin Lipset, David Lockwood, and Peter Townsend). The question that underlies this early literature, whether the equalizing principles of citizenship can, and do, eliminate the inequalities of social class and incorporate the excluded into the national collectivity as equal members, still occupies a prime place in the sociological imagination, if only asked differently to include other excluded bodies of citizens (women, and diverse contingents of cultural, sexual, racial, and ethnic minorities).

Marshall saw modern citizenship as a product of a larger societal transformation through which "[d]ifferential status, associated with class, function and family was replaced by the single uniform status of citizenship, which provided the foundation of equality on which the structure of inequality could be built" (1964: 87–88). It is this tension between the expected transforming capacity of citizenship and the continuing inequalities of the modern society that makes Marshall's work still relevant.

T.H. Marshall and Citizenship Today

The concept of citizenship has lived a major intellectual and political renaissance in the aftermath of the political upheavals of the 1990s, mainly in response to the rebirth of new nation-states and the restructuring of the relationship between states and their citizens. These developments have laid bare the differentials in membership and right-bearing, and exposed the limits of citizenship. The theoretical repository set by Marshall's oeuvre has been the point of departure for the new bourgeoning interest in citizenship. At the current state of citizenship scholarship, it is unavailing to expect a publication that does not have a reference to Marshall's *Citizenship and social class*. Whether critically appraised or endorsed, what is striking is how much the recent conceptualizations of citizenship still owe to that of Marshall's.

Three main lines of criticism warrant consideration if only to reveal the influence of Marshall's work on the current undertakings on citizenship. Not so surprisingly, the most scrutinized aspect of Marshall's sociology of citizenship is its evolutionary character. Marshall's periodization of the rise of citizenship has come under attack for not allowing for alternative paths of progression. Moving from different analytical concerns and focusing on different empirical cases, research in historical sociology provides comparative contrast to Marshall's sequence (Turner, 1986; Mann, 1987; Barbalet, 1988; Somers, 1993). In this body of scholarship, attention to the existing political regimes, the strategies of the ruling elites and the ruled classes, and the varying institutional arrangements and patterns of associational and participatory forms, at both local and national levels, sanctions the redefinition of parameters and trajectory of citizenship. The path to citizenship, as it is evinced by these critical inquiries, is nowhere single and predetermined. Particularly revealing is the movement and importance that social rights displayed in the citizenship schemes of other countries. Bismarckian social reforms, for example, were introduced as substitute for full political citizenship (Mann, 1987). In Germany, not only the social rights preceded political rights, but also the imperative relationship between the two sets of rights that Marshall postulated based on the British case was not there.

Even the British case may not fit neatly with Marshall's periodization, it is argued. The empirical reanalysis of the English citizenship practices in the seventeenth and eighteenth centuries reveals that the emergence of national labor markets and development of civil rights happened in the company of extensive 'claims to and practices of political and social citizenship.' These claims and practices were then, under right conditions, transformed into explicit rights for English working class communities (Somers, 1993). Said otherwise, political and social citizenship materialized in varying intensity but significantly before the time frame predicted by Marshall's scheme.

Here, a second line of criticism to Marshall surfaces; the lack of agency and struggle in Marshall's explanatory framework. His explanation of citizenship rights relies on the dynamic tension between citizenship and social class in the framework of capitalist market development. Marshall's stages of citizenship progress with the formative demands of each emerging social class, but this class agency remains implicit in the main (Somers, 1993). In much of the scholarship that follows Marshall's steps class agency, or agency as such, does not get a proper treatment either. In this literature, citizenship is conceptualized as a personal status or legal category, which

guarantees equal rights and exact obligations for individuals in national polities. Inasmuch as the scholarship on citizenship moves away from this legalistic/formalistic take on rights and membership, they reveal a much more dynamic understanding of the citizenship development. The active agency is then reconstituted in the analysis of the evolution and elaboration of citizenship as a complex set of rights, statuses, and practices.

An approach which privileges the agency and participatory practices, for instance, effectively unearths women's place in the realm of citizenship, a social group that does not have visibility in the Marshallian framework. In the United States, despite being denied the franchise, women groups were able to mobilize successfully for mother's pensions and other legislation in the Progressive era (Skocpol, 1992). This finding not only reverses Marshall's sequential analysis, but also remedies the accounts of citizenship, which omit the formative role of women and their movements in the historic progress of citizenship.

Rights formation is not only a result of contradictions between the egalitarian principles of citizenship and capitalist society, as Marshall's account articulates (Barbalet, 1988). Citizenship is actively created by the participation of people in interaction with formal institutions and power structures (Turner, 1986, 1990). With this revision, that is, the expansion of Marshallian model to include 'citizenship from below,' the citizen enters the public space as an actor, 'an active bearer of claims,' and partakes in popular struggles to acquire rights. The resulting model thus resolutely incorporates the agency and mobilization of societal groups into the developmental framework cultivated by Marshall and his exponents.

The third line of criticism takes Marshall's framework to test at the end of the millennium. Marshall wrote his account of citizenship when national character of the state and welfare regimes was taken for granted. Even though Marshall was not so much attentive to the formation of the 'national' content of citizenship, nevertheless, he was aware that "the citizenship whose history [he wished to trace was], by definition, national" (1964: 72). The extension of socioeconomic rights to the previously excluded groups of people, such as the working class, facilitates their incorporation into the 'common culture' of the national collective. Marshall does not elaborate on this collective, neither does he take it to task to define what holds this collective together and what defines the boundaries of this collective.

A necessary corrective to the study of citizenship, brought to fore through empirical and theoretical treatments, has been to redefine citizenship from simply a legal status to a body of membership forms and practices (Brubaker, 1992; Soysal, 1994; Kymlicka, 1995). This shift in focus has brought with it a heightened and productive debate, with attention to historical and contemporary processes of boundary making, and the sources of inclusion and exclusion. As revealed by this debate, citizenship, which has evolved to encompass 'national' collectivities, variously following distinct paths and forming peculiar traditions, is no longer singularly located within national boundaries. Neither the distribution of membership rights relies on 'national' belonging as the indispensable criterion. Nor the citizenship practices are delimited by the boundaries of the nation-state within which the citizens reside. This *fin de siècle* reconstitution of citizenship implies a multiplicity of membership. In the new terrain of citizenship, different categories of members are accorded with differentiated set of rights – thus breaching the principle of uniform citizenship rights and accentuating disparities between members. Also in the new citizenship claims to rights and citizenship expand beyond the conventional modalities of political, civil, and social to embrace cultural, sexual, ecological, and global citizenships. The claims are increasingly advanced, and legitimated, by appeals to group differences but on the basis of universalistic human rights, as codified in transnational treaties and conventions. And the collectives and individuals organize and mobilize their claims not only at local and national but also transnational levels, targeting a variety of governing bodies (such as the European Court of Human Rights).

More recently, the manifest predominance of human rights frameworks but also their faltering reach has renewed questions about the relationship between rights and social justice – a long-standing concern in Marshall's scholarship. The debates in the newly invigorated sociology of rights revisit the relationship between citizenship and human rights, forcing to the forefront such issues as recognition, solidarity, and substantive enjoyment of rights (for various treatments see Somers, 2008; Nash, 2009; Walby, 2009; Morris, 2010). Much of these debates treat the relationship between citizenship and human rights contentious. Often the universal and natural character of (globally sanctioned) human rights is juxtaposed with the particularistic and political nature of (nation-state based) citizenship. The potential of human rights for furthering effective justice is questioned, on the grounds that they lack institutionalized enforcement mechanisms beyond the nation-state itself and they lack the solidarity to which national citizenship historically laid claim. While such juxtapositions inevitably warrant paying closer attention to the entangled practice of human rights and citizenship in the postwar period, at the same time, they underscore the broader analytical question of 'what rights do' (Soysal, 2012).

This is where T.H. Marshall reenters into our sociological conversations. For Marshall, rights in themselves did not have any inherent quality. Rights, he argued, are means for inclusion, which could be guaranteed only with their grounding in effective membership institutions – in other words the very social and institutional arrangements in which the projected citizenship of persons is recognized and the very possibility of a right exists. It is exactly these arrangements that are under threat today, laying bare the vulnerabilities of individuals, citizens, and noncitizens alike. Drawing on T.H. Marshall, Somers and Roberts (2008: 388) insightfully remind us that rights exist at 'multiple registers': as normative aspirations, codification and doctrine, and mechanisms and institutions of implementation. Human rights chart along all three of these registers; so do citizenship rights. Thinking along these three registers, we are able see that even 'the most formalized rights-bearing subject is incomplete' and citizenship is an 'incompletely theorized contract' between the state and the individual (Sassen, 2006: chapter 6). The increasing normative and cognitive authority accorded to human rights in national and transnational conventions in turn exposes the limits and 'incompleteness' of citizenship

projects, revealing them as contingent accomplishments, and opening up possibilities for expansion. It is this dynamic tension between the normative standards and practice of rights that gives much significance to the institution of citizenship and its potential for justice today, as ever before.

As his critiques have pointed out, the developments at the beginning of the twenty-first century project a significantly different topography of citizenship than the one analyzed and conceptualized by Marshall. As citizenship, and its associated rights, expands and differentiates within and without the nation-state, one may be impatient to register the infirmities and imperfections of Marshall's account. One may promptly find him guilty of not providing all the right answers. However, at the end, an eventual return to Marshall is only inevitable and fitting. His grand narrative of citizenship paves the way for lucid analyses of the new terrains of citizenship that confront us. Through conversations and argumentation with Marshall, the formations of new citizenship become manifestly tangible and substantive. And ultimately it is his preoccupation as a scholar and citizen that motivates our continuing interest in citizenship – that inequalities, independent of their sources and forms, are still part of our scholarly and societal agendas, and still take us, the sociologists, to task.

Martingales

René L Schilling, Institut für Mathematische Stochastik, Technische Universität Dresden, Dresden, Germany

Abstract

A martingale is the mathematical description of a fair game: The expected net gain or loss from further play, independent of the history, is 0. The rigorous mathematical definition involves conditional expectation. Following earlier work by Paul Lévy and Jean Ville, Joseph Leo Doob developed in the 1940s and 1950s basic martingale theory and many of its applications. Martingales allowed one to study, for the first time, the behavior of sums and sequences of random variables which are not independent. Martingale theory is one of the cornerstones of modern mathematical probability theory with wide-ranging applications in stochastic analysis and mathematical finance.

The notion of *martingale* is intimately connected with that of a *fair game* where the player and the bank have equal chances of winning. In the eighteenth and nineteenth centuries, a martingale meant a gambling strategy; in its simplest form a player doubles his stake if he lost in the previous round, and stops playing otherwise. Under the assumption that the player can bet indefinitely high stakes, the losses are given by a geometric progression and, after possibly arbitrarily high losses, there is a guaranteed net win of the *initial* stake. This is equivalent to the so-called *St. Petersburg paradox* (Gorroochurn, 2012). Usually this strategy fails due to limited wealth of the player, time constraints, and limits on the stakes on the side of the casino: The mean loss (prior to winning) is infinite.

In mathematical terms, the fair game underlying a simple martingale is a sum of independent, identically distributed Bernoulli random variables $Y_1, Y_2, \ldots$ such that $\mathbb{P}(Y_n = -1) = \mathbb{P}(Y_n = 1) = \frac{1}{2}$ (e.g., representing the nth toss of a fair coin); $Y_n = 1$ returns twice your stake, while $Y_n = -1$ means you lose all. Denoting by $e_1 = 1$ and $e_n = e_n(Y_1, \ldots, Y_{n-1})$, $n = 2, 3, \ldots$, the stake for the nth game, the total net winnings are $X_0 = 0$ and $X_n = e_1Y_1 + \ldots + e_nY_n$. One easily sees that the conditional expectation (Schilling, 2005; Schilling and Partzsch, 2014; Williams, 1991) satisfies

$$\mathbb{E}(X_{n+1}|Y_1, \ldots, Y_n) = X_n \qquad [1]$$

Since the events $(Y_i = \pm 1)$ have strictly positive probability, this abstract conditional expectation still has its classical meaning as

$$\mathbb{E}(X_{n+1}|Y_1 = y_1, \ldots, Y_n = y_n) = x_n$$

where the y_i, $i = 1, \ldots, n$, are the outcomes of the rounds $1, \ldots, n$, and $x_n = e_1y_1 + e_2(y_1)y_2 + \ldots + e_n(y_1, \ldots, y_{n-1})y_n$ is the net win after the nth round. Iterating eqn [1] yields

$$\mathbb{E}(X_{n+k}|Y_1, \ldots, Y_n) = X_n \quad k, n = 1, 2, \ldots \qquad [2]$$

The simple martingale strategy corresponds to the stakes $e_1(-1, -1, \ldots, -1) = 2^{n-1}$ and 0 in all other cases. In particular, the expected gains are

$$\mathbb{E}X_n = \mathbb{E}X_{n-1} = \ldots = \mathbb{E}X_0 = 0$$

Conditional expectation can be interpreted as the best mean-square predictor for the future win X_{n+k} conditional on the past outcomes $Y_1, \ldots, Y_n$. Since the stakes for the next round depend only on the past results, i.e., e_{n+1} is a function of $Y_1, \ldots, Y_n$, the stakes are previsible. The martingale property guarantees that the best prediction is always the current (time n) level of winnings. In this sense, a martingale describes a fair game.

It is not possible to change the character of a game by a previsible gambling strategy: A fair game will stay fair no matter which gambling strategy is being used. This follows immediately from the fact that in the discussion above we have made no further assumptions on the gambling strategy, i.e., the stakes $e_1, e_2, \ldots$, than previsibility. The same assertion is true for favorable [unfavorable] games that are submartingales [supermartingales].

Definition

The *general definition of a martingale* is as follows: Given a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, an index set I equipped with a partial order $s \le t$ and an increasing family of σ-algebras (a *filtration*) $\mathcal{F}_s \subset \mathcal{F}_t \subset \mathcal{F}$ if $s \le t$, then the real-valued random variables $(X_t)_{t\in I}$ are a *martingale* with respect to $(\mathcal{F}_t)_{t\in I}$, if each X_t is $\mathcal{F}_t$ measurable, $\mathbb{E}|X_t| < \infty$ for all $t \in I$, and

$$\mathbb{E}(X_t|\mathcal{F}_s) = X_s \quad \text{for all} \quad s, t \in I, s \le t \qquad [3]$$

if we replace '=' by '$\ge$' [or '$\le$'], we get a sub- [or super-] martingale.

The expectation $m(t) = \mathbb{E}X_t$ of a martingale is constant, while those of a sub-/supermartingale are increasing/decreasing functions of t.

A *downward*, *backwards* or *reversed martingale* is a martingale where the family of σ-algebras $(\mathcal{F}_t)_{t\in I}$ decreases as t increases. This means that $(X_{-t}, \mathcal{F}_{-t})_{t\in -I}$ is a martingale (with the natural order of $-I$) and all martingale results hold for backwards martingales. Therefore, there is no need to distinguish between martingales and backwards martingales. If I has a smallest element, i_0, then $-I$ has a largest element and the backwards martingale is right-closed, i.e., $X_{-t} = \mathbb{E}(X_{i_0}|\mathcal{F}_{-t})$ for all $t \in -I$. Backwards martingales were first studied in Doob (1953).

The notion of a (sub-/super-) martingale essentially depends on the given stochastic basis $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge 0}, \mathbb{P})$. If $(X_t)_{t\in I}$ is a martingale for the filtration $(\mathcal{F}_t)_{t\in I}$, it is also a martingale for the minimal σ-algebras $\mathcal{F}_t^X = \sigma(X_s : s \le t, s \in I)$

which is, by definition, the smallest σ-algebra such that all X_s, $s \le t$, are measurable. A further reduction is not possible.

On the other hand, enlarging the filtration usually results in the loss of the martingale property: The σ-algebra $\mathcal{F}_t$ has a natural interpretation as 'the information until time t' and enlarging $\mathcal{F}_t$ means increasing the available information (e.g., because of insider knowledge or cheating) which immediately leads to a nonfair situation.

In eqns [1] and [2] one uses the σ-algebra $\sigma(Y_1, \dots Y_n)$ which is generated by $Y_1, \dots Y_n$. Changing to the smaller σ-algebras $\sigma(X_1, \dots X_n)$, one would still get a martingale, since both $\sigma(Y_1, \dots Y_n)$ and $\sigma(X_1, \dots X_n)$ contain the essential information on the game. Indeed, X_n is a function of the $Y_1, \dots Y_n$, while

$$e_{n+1}(Y_1, \dots, Y_n)Y_{n+1} = X_{n+1} - X_n$$

this allows one to represent $Y_1, Y_2, \dots$ – on the sets where e_1, $e_2, \dots$ are strictly positive–recursively in terms of $X_1, X_2, \dots$.

For simplicity, we will assume that $I \subset [0, \infty]$. Integer indices are usually denoted by m or n, real indices by s, t.

Examples

In the examples $\mathcal{F}_t^X = \sigma(X_s : s \le t, s \in I)$ denotes the minimal filtration of the process $(X_t)_{t \in I}$.

1. (Sum of independent random variables) $X_n = Y_1 + \dots + Y_n$, $X_0 = 0$, where $(Y_n)_{n \in \mathbb{N}}$ are real-valued, independent, mean-zero random variables, is a martingale with filtration $\mathcal{F}_n^X = \mathcal{F}_n^Y$. If $\mathbb{E}Y_n \ge 0$ (≤ 0) for all n, then $(X_n)_{n \in \mathbb{N}_0}$ is a submartingale [supermartingale].
   If $\mathbb{E}(X_n^2) < \infty$ for all $n \in \mathbb{N}_0$, then $(X_n^2)_{n \in \mathbb{N}_0}$ is a submartingale and $(X_n^2 - \mathbb{E}(X_n^2))_{n \in \mathbb{N}_0}$ is a martingale with filtration $(\mathcal{F}_n^X)_{n \in \mathbb{N}_0}$.
2. (de Moivre's martingale) Let $(Y_n)_{n \in \mathbb{N}}$ be independent identically distributed random variables such that $\mathbb{P}(Y_n = 1) = p$ and $\mathbb{P}(Y_n = -1) = q = 1 - p$. Then $(X_n)_{n \in \mathbb{N}_0}$ with $X_0 := 1$ and $X_n := (q/p)^{Y_1 + \dots + Y_n}$ is a martingale for the filtration $(\mathcal{F}_n^Y)_{n \in \mathbb{N}}$.
3. (Wald martingale) Let $(Z_n)_{n \in \mathbb{N}}$ be nonnegative independent random variables with finite means $\mu_n = \mathbb{E}Z_n > 0$. Then $(X_n)_{n \in \mathbb{N}_0}$ with $X_0 := 1$ and $X_n := \prod_{i=1}^n \mu_i^{-1} Z_i$ is a martingale for the filtration $(\mathcal{F}_n^Z)_{n \in \mathbb{N}_0}$.
4. (Pólya's urn) An urn contains X_0 blue and Y_0 red balls. Draw randomly a ball from the urn. If a blue (resp. red) ball is drawn, replace the ball and add c more blue (resp. red) balls to the urn. Denote by X_n and Y_n the number of blue and red balls in the urn after the nth round. Then $(V_n)_{n \in \mathbb{N}_0}$ with $V_n = X_n/(X_n + Y_n)$ is a martingale for the filtration $\mathcal{F}_n := \sigma(X_i, Y_i : i \le n)$. (Pólya invented this scheme in order to model the spread of contagious diseases.)
5. Let $(X_t)_{t \ge 0}$ be a stochastic process with independent increments such that $m(t) = \mathbb{E}X_t$ exists. It is a martingale (with filtration$(\mathcal{F}_t^X)_{t \ge 0}$) if, and only if, $m(t)$ is constant; it is a submartingale if, and only if, $m(t)$ is increasing.
   The process $(X_t - m(t))_{t \ge 0}$ is a martingale. In particular, one-dimensional Brownian motion $(W_t)_{t \ge 0}$ and the compensated Poisson process $(N_t - \lambda t)_{t \ge 0}$ with intensity $\lambda > 0$ are martingales.
6. (Exponential martingale) Let $(X_t)_{t \ge 0}$ be a real-valued Lévy process (a process with independent and fixed increments which is continuous in probability). Then $(\exp(i\xi X_t)/\mathbb{E}e^{i\xi X_t})_{t \ge 0}$, $\xi \in \mathbb{R}$, is a martingale for the filtration $(\mathcal{F}_t^X)_{t \ge 0}$.
7. Let $(X_n)_{n \in \mathbb{N}_0}$ be a Markov chain with countable state space E and transition matrix $\mathrm{P} = (\mathrm{p}_{ik})_{i,k \in E}$. Then, for any $u : E \to \mathbb{R}$, $(u(X_n) - \sum_{m=0}^{n-1}(\mathrm{id} - P)u(X_m))_{n \in \mathbb{N}_0}$ is a martingale with filtration $(\mathcal{F}_n^X)_{n \in \mathbb{N}_0}$.
   If u is invariant for P, i.e., $Pu \equiv u$, then $(u(X_n))_{n \in \mathbb{N}_0}$ is again a martingale.
8. Let $(X_t)_{t \ge 0}$ be a Markov process with transition semigroup $(P_t)_{t \ge 0}$ and generator A. Then $(u(X_t) - \int_0^t Au(X_s)\mathrm{d}s)_{t \ge 0}$ is for any $u : \mathbb{R} \to \mathbb{R}$ from the domain of A a martingale with filtration $(\mathcal{F}_t^X)_{t \ge 0}$.
   If u is A-harmonic, i.e., $Au \equiv 0$, then $(u(X_t))_{t \ge 0}$ is again a martingale.
9. (Lévy martingale, closed martingale) Let $(\mathcal{F}_t)_{t \ge 0}$ be an increasing family of σ-algebras in $\mathcal{F}$ and X be a real-valued random variable with $\mathbb{E}|X| < \infty$. Then $(X_t)_{t \ge 0}$ where $X_t := \mathbb{E}(X|\mathcal{F}_t)$ is a uniformly integrable martingale. Since $X = X_\infty$ is the right endpoint, this martingale is often called a *(right-)closed* martingale.
10. Let $\mathbb{Q}$ be a further probability measure on $(\Omega, \mathcal{F})$, let $(\mathcal{F}_t)_{t \ge 0}$ be an increasing family of σ-algebras in $\mathcal{F}$ and denoted by $\mathbb{Q}_t$ and $\mathbb{P}_t$ the restrictions of the measures $\mathbb{Q}$ and $\mathbb{P}$ to $\mathcal{F}_t$. The *likelihood ratio* $L_t := \mathrm{d}\mathbb{Q}_t/\mathrm{d}\mathbb{P}_t, \quad t \ge 0$, is a nonnegative martingale.

Properties

(Schilling, 2005; Schilling and Partzsch, 2014; Revuz and Yor, 1999; Rogers and Williams, 1987/94; Williams, 1991; Chow and Teicher, 1997) (Sub-)martingales have good convergence properties: If $\sup_{t \in I}\mathbb{E}|X_t| < \infty$ and $t \to t_0 \in I$, then $X_t \to X_{t_0}$ almost surely; if $(X_t)_{t \in I}$ is a uniformly integrable (sub-)martingale, this convergence holds also in L^1-sense. In particular, all uniformly integrable martingales are of the form of Example 9 with $X = \lim_{t \to \infty} X_t$, and vice versa. A sufficient condition for uniform integrability is that $\sup_{t \in I}\mathbb{E}(|X_t|^p) < \infty$ for some $p > 1$. The convergence properties make martingale techniques powerful tools to get càdlàg (i.e., right-continuous with finite left limits) modifications of continuous-time stochastic processes. In the sequel, we will only consider càdlàg modifications.

If $(X_t)_{t \in I}$ is a martingale and $\phi : \mathbb{R} \to \mathbb{R}$ a convex function with $\mathbb{E}|\phi(X_t)| < \infty$ for all $t \in I$, then $(\phi(X_t))_{t \in I}$ is a submartingale. For (positive sub-)martingales we have *Doob's maximal inequalities*

$$\mathbb{E}\left(\sup_{t \in I} |X_t|^p\right) \le c_p \sup_{t \in I} \mathbb{E}\left(|X_t|^p\right)$$

with $c_p = (p/(p-1))^p$ and $1 < p < \infty$.

Martingale convergence theorems were the first convergence results for sums and sequences of random variables which are *not* independent. Even nowadays, martingale techniques are among the most successful methods to deal with dependent random variables. For example the Lindeberg–Feller central limit

theorem admits a martingale version: Let $F_0 := \{\emptyset, \Omega\}$, $(\mathcal{F}_n)_{n\in\mathbb{N}}$ be a filtration and $(X_n)_{n\in\mathbb{N}_0}$ be a sequence of L^2-martingale differences (i.e., $\mathbb{E}(X_n^2) < \infty$ and $\mathbb{E}(X_{n+1}|\mathcal{F}_n) = 0$ for all $n \in \mathbb{N}_0$), set $\sigma_n^2 = \mathbb{E}(X_n^2)$ and $s_n^2 = \sigma_1^2 + \ldots + \sigma_n^2$. If $(X_n)_{n\in\mathbb{N}_0}$ satisfies the Lindeberg condition and

$$\sum_{i=1}^{n} \mathbb{E}\left|\mathbb{E}\left(X_i^2 \middle| \mathcal{F}_{i-1}\right) - \sigma_i^2\right| = o(s_n)$$

then $s_n^{-1}\sum_{i=1}^n X_i$ converges in distribution to a standard normal random variable. An analogous martingale version exists for the *Berry–Esseen theorem*.

A *stopping time* (also: Markov time or optional time) is a random time $\sigma : \Omega \to I \cup \{\infty\}$ that is adapted to a given filtration $(\mathcal{F}_t)_{t\in I}$ in the sense that $\{\omega : \sigma(\omega) \le t\} \in \mathcal{F}_t$ for all $t \in I$; this means that it is enough to know X_s for all $s \le t$, $s, t \in I$, in order to decide whether $\sigma \le t$ or not. If $(X_t)_{t\in I}$ is a uniformly integrable martingale and $\sigma \le \tau$ are stopping times with values in I, then eqn [3] still holds for random times $\sigma \le \tau < \infty$ (*optional stopping*); in particular, the stopped process $X_t^\tau := X_{\min(t,\tau)}$ is a martingale both for $(\mathcal{F}_t)_{t\in I}$ and $(\mathcal{F}_{\min(t,\tau)})_{t\in I}$ (*optional sampling*).

The fundamental relationship between martingales and submartingales is the *Doob–Meyer decomposition*: If $(X_t)_{t\ge 0}$ is a càdlàg submartingale of *class D* (i.e., the family $\{X_\tau : \tau$ finite stopping time$\}$ is uniformly integrable), then there exists a unique (up to indistinguishability), increasing, previsible (in a continuous-time setting *previsible* means that the process $(A_t)_{t\ge 0}$ is measurable with respect to the σ-algebra generated by all left-continuous adapted processes. In particular, any left-continuous process $(Y_t)_{t\ge 0}$ such that Y_t is $\mathcal{F}_t$ measurable is previsible) process $(A_t)_{t\ge 0}$, $A_0 = 0$, and a uniformly integrable martingale $(M_t)_{t\ge 0}$, $M_0 = 0$, such that $X_t = X_0 + A_t + M_t$. Without the assumption of *class D*, we still have a unique decomposition into an increasing previsible process A_t and a *local* martingale M_t. Local martingales are processes for which there is a sequence of stopping times τ_n converging almost surely to infinity as $n \to \infty$ and such that $(M_t^{\tau_n})_{t\ge 0}$ are, for each $n \in \mathbb{N}$, martingales.

Examples (7) and (8) point to the connection of martingales with potential theory. Recall that the Laplacian $\frac{1}{2}\Delta$ is the generator of Brownian motion $(W_t)_{t\ge 0}$. Thus, a (classical) harmonic function $u \in C^2(\mathbb{R}^n)$ satisfies $\Delta u \equiv 0$ and $(u(W_t))_{t\ge 0}$ is a martingale. Similarly a subharmonic function u produces a submartingale. The Doob–Meyer decomposition is the stochastic analogue of the Riesz decomposition (any superharmonic function can be written as the sum of a harmonic function and a potential) from potential theory.

Martingale theory and the Doob–Meyer decomposition were instrumental for the development of a general theory of stochastic (Itô) integrals. Let $(M_t)_{t\ge 0}$ be an L^2-martingale, i.e., $\mathbb{E}(|M_t|^2) < \infty$ for all $t \ge 0$. By the Doob–Meyer decomposition there is a unique increasing previsible process $\langle M\rangle_t$ such that $M_t^2 - \langle M\rangle_t$ is a martingale; $\langle M\rangle_t$ is called the (*previsible*) *compensator* or *angle bracket* of $(M_t)_{t\ge 0}$. If $t \mapsto M_t$ is almost surely continuous, then there is a simple formula for the angle bracket: Denoting by Π a partition $0 = t_0 < t_1 < \ldots < t_n = t$ of $[0, t]$ with mesh $|\Pi| = \max_{1\le i\le n}(t_i - t_{i-1})$, then

$$\langle M\rangle_t = \lim_{|\Pi|\to 0} \sum_{i=1}^{n} (M_{t_i} - M_{t_{i-1}})^2$$

(the limit is in the sense of local uniform convergence in probability). For a martingale with jumps $\Delta M_s = M_s - M_{s-}$, $M_{s-} = \lim_{r<s, r\to s} M_r$, and continuous part M_t^c one has

$$\sum_{s\le t} (\Delta M_s)^2 + \langle M^c\rangle_t = \lim_{|\Pi|\to 0} \sum_{i=1}^{n} (M_{t_i} - M_{t_{i-1}})^2$$

For instance, one-dimensional Brownian motion $(W_t)_{t\ge 0}$ satisfies $\langle W\rangle_t = t$, and for a Poisson process $(N_t)_{t\ge 0}$ of intensity λ and the associated martingale $M_t = N_t - \lambda t$ one has $\langle M\rangle_t = \lambda t$. In fact, *Lévy's martingale characterization of Brownian motion* says that a one-dimensional Brownian motion is the only (local) martingale in continuous time and with continuous paths such that $\langle W\rangle_t = t$ and $W_0 = 0$. A result by Doeblin, Dambis, and Dubins–Schwarz tells us that every L^2-martingale $(M_t)_{t\ge 0}$ with continuous paths can be embedded into a (suitable) Brownian motion by $M_t = M_0 + W_{\langle M\rangle_t}$.

In the guise of Itô's isometry (see below) quadratic variations can be used to define the stochastic integral driven by a martingale $(M_t)_{t\ge 0}$ with filtration $(\mathcal{F}_t)_{t\ge 0}$. A *simple* or *elementary process* $(Y_t)_{t\ge 0}$ is a bounded càdlàg process with finitely many values

$$Y_t(\omega) = \sum_{i=0}^{n-1} \eta_i(\omega) 1_{[t_i, t_{i+1})}(t), \quad t \ge 0, \omega \in \Omega$$

where $t_0 = 0 < t_1 < \ldots t_n <$ and η_i is a $\mathcal{F}_{t_i}$ measurable random variable. Then

$$\begin{aligned} Y\cdot M_t &= \int_0^t Y_{s-}\,\mathrm{d}M_s \\ &:= \sum_{i=0}^{n-1} \eta_i \left(M_{\min(t_{i+1},\, t)} - M_{\min(t_i,\, t)}\right) \end{aligned}$$

defines the Itô integral and $(Y\cdot M_t)_{t\ge 0}$ is an L^2-martingale; its compensator $(\langle Y\cdot M\rangle_t)_{t\ge 0}$ is given by $\int_0^t |Y_{s-}|^2 \mathrm{d}\langle M\rangle_s$. The compensator property yields the *Itô isometry*

$$\mathbb{E}\left\{\left(\int_0^t Y_{s-}\,\mathrm{d}M_s\right)^2\right\} = \mathbb{E}\int_0^t |Y_{s-}|^2 \mathrm{d}\langle M\rangle_s$$

which allows one to extend the stochastic integral by continuity to all càdlàg integrands such that Y_t is $\mathcal{F}_t$ measurable, $t \ge 0$, and $\mathbb{E}\int_0^T |Y_{t-}|^2 \mathrm{d}\langle M\rangle_t < \infty$.

The development of stochastic analysis gave rise to further generalizations of martingales: Local martingales and semimartingales (Revuz and Yor, 1999; Rogers and Williams, 1987/94). Martingales also turned out to be a powerful tool in characterizing and constructing Markov processes. The key role in these *martingale problem* approaches (Stroock and Varadhan, 1997; Ethier and Kurtz, 1986; Böttcher et al., 2013) is the observation that the martingales appearing in Examples 7 and 8 characterize the underlying Markov chains and processes.

Applications

Martingales have found many important applications also outside of probability theory.

One of the most prominent applications is in mathematical finance in the theory of *arbitrage* and *risk-neutral pricing* of

financial assets (Bingham and Kiesel, 1998). In a market, an arbitrage opportunity is a trading strategy that has a positive probability of winning and zero probability of losing money. It is a money-making machine, the ultimate unfair game. On the other hand, a martingale represents a fair game and will not allow for arbitrage. Since one can always invest in riskless interest-bearing bonds, it is clear that one has to discount prices by a numéraire, e.g., to divide asset prices by the price of the riskless bond. A *martingale measure* is a probability measure $\mathbb{Q}$ such that the discounted asset prices form a martingale. In a real market, no player (with their own beliefs, expressed by the player's own probability measure $\mathbb{P}$, sometimes called the real-world probability measure) expects the asset prices to be martingales since no one gains by betting on a martingale. On the other hand, in many situations there is an equivalent (with respect to $\mathbb{P}$) martingale measure $\mathbb{Q}$ such that the discounted asset prices become martingales under the conditional expectations induced by $\mathbb{Q}$. By *the fundamental theorem of asset pricing* the existence of a martingale measure guarantees that there is no arbitrage. Moreover, the market is complete (i.e., each derivative can be 'hedged' or 'replicated' by a trading strategy) if the martingale measure is unique. In a discrete-time setting the existence of an equivalent martingale measure is even equivalent to an arbitrage-free complete market. In the classical Black–Scholes model where the asset prices are modeled by a geometric Brownian motion, it is always possible to find a martingale measure $\mathbb{Q}$ with the help of Girsanov's theorem. In order to calculate the fair price of a derivative (e.g., a share option) one performs the following steps: First one determines the pay-off of the derivative, then one constructs an equivalent martingale measure $\mathbb{Q}$, finally the discounted price process of the derivative is the expectation (under $\mathbb{Q}$) of its payoff; since everything is, by construction, a martingale, no arbitrage is possible.

Within mathematics, martingales turn out to be useful in the study of almost everywhere convergence. Typical applications include the *geometry of Banach spaces* and *Littlewood–Paley theory*. An unconditional basis in a Banach space B is a basis $(e_n)_{n\in\mathbb{N}}$ such that every rearrangement of the series $\sum_n a_n e_n$ converges to the same limit $b \in B$. The spaces $L^p((0,\ 1),\ \mathrm{d}x)$ have the Haar functions as unconditional basis if, and only if, $1 < p < \infty$. This can be checked by martingale arguments involving the Burkholder–Davis–Gundy inequalities and so-called martingale difference sequences: $(e_n)_{n\in\mathbb{N}}$ is a martingale difference sequence if $\mathbb{E}(e_{n+1}|\sigma(e_1, \ldots, e_n)) = 0$. In fact, the Haar functions are an unconditional basis for every rearrangement-invariant function space which is isomorphic to a Banach space with an unconditional basis. This is the basis for many structure and embedding results for Banach spaces.

In the theory of vector measures, the L^1-martingale convergence theorem (for Banach space valued martingales) is equivalent to the Radon-Nikodým property of a Banach space B, i.e., every function f: $[0,\ 1] \to B$ of bounded variation is almost everywhere differentiable or, equivalently, every separable subspace of B has a separable dual.

If a function space has an orthonormal basis consisting of martingale differences, one can often use the pointwise martingale convergence theorem and maximal inequalities to obtain pointwise almost everywhere convergence results (Schilling, 2005: Chapter 24). In harmonic analysis (Stein, 1993, pp. 184–192) there are deep connections with (maximal) inequalities for the Littlewood–Paley functions and the Hilbert transform leading to proofs of Carleson's famous result that the Fourier series of a square-integrable function converges almost everywhere. In the theory of bounded mean oscillation (BMO) spaces, martingale maximal inequalities are most powerful tools. For example, one can prove the John–Nirenberg estimates for BMO spaces and Fefferman's theorem: BMO is the dual of the Hardy space H^1.

Historical Notes

Jean Ville (1936, 1939) introduced the term 'martingale' into probability. In his 1936 definition he considered only martingales of the form $X_n = e_1Y_1 + \ldots + e_nY_n$ (as in the second paragraph of this article) which he generalized in the monograph 1939 both in the time-discrete and time-continuous case. Ville used martingales to discuss *the concept of a collective, upon which many mathematicians found the theory of probability*. [...] *This leads* [...] *to a new definition of collective* (Doob, 1939). Ville's approach to von Mises' theory of collectives interprets the complete irregularity in a random sequence as the impossibility of a successful gambling system of 'martingale' type (in the classical sense of the first paragraph). In fact, von Mises (1932, pp. 157–158) already contains elements of this line of thought, and martingales are explicitly mentioned – however, as gambling systems only. The first general definition of martingales using conditional probabilities and the first ever martingale convergence theorem (*Lévy's 0–1 law*) can be found in Lévy (1937, pp. 122–123 (definition), p. 129, Theorème 41). Ville's 1939 definition follows (Lévy, 1937) and it is very close to the first 'modern' definition in Doob (1940) who calls eqn [3] *condition* ε (seemingly using Lévy's slightly obscure diction). It was mainly Doob who pioneered the theory and applications of martingales and his groundbreaking monograph (Doob, 1953) contains most of the basic results on martingales. Subsequently, major contributions to the theory, in particular in the connection with stochastic calculus, are mainly due to the French and Japanese schools of probability, see Meyer (1966), Dellacherie and Meyer (1980), Kunita and Watanabe (1967), and Ikeda and Watanabe (1981).

Etymology

According to the *Oxford English Dictionary* (OED) www.oed.com (Accessed online 20 July 2014.) the etymological origin of the word martingale is unclear. Most likely it derives from *martengala*, feminine of martegal/martengal, an inhabitant of Martigues (a small town in south-eastern France, département Bouches-du-Rhône). The word martingale has been used in the following senses:

1. *Horse riding*. A strap or harness preventing the horse from rearing or throwing its head back.
2. *Nautical*. Any part of a rigging strengthening the jib boom and bowsprit of a ship.

3. A dog collar made of two loops. When the animal tries to pull, the loop around the dog's neck contracts without the choking effect of a slip collar.
4. *Clothing*. (a) A loose half-belt or strap on the back of a garment. (b) A pair of trousers.
5. *Games*. A gambling system as described in the introduction to this article.
6. *Mathematics*. A stochastic process as described in this article.

The earliest use is in French as in 1 and 4(b). The OED states that "[t]he application may arise from a belief that the inhabitants of Martigues, a remote town, were eccentric and naive; hence also the application to an apparently foolish system of gambling. Sense two, however, is probably attributable to the former importance of Martigues as a port and ship-building center." An in-depth discussion on the origins of the word martingale can be found in Mansuy (2009).

Abstract

Maruyama Masao described himself as a "man with no talent other than scholarship" whose 'main business' was the study of East Asian, especially Japanese, political thought. As such he belongs among the most influential Japanese historians of the twentieth century. But the history he lived had also compelled him to open what he called a 'night stall' as a political scientist, activist intellectual, and perhaps the preeminent imaginer of democracy in Japan since 1945. Characterized variously as a modernist, national democrat, or simply as a liberal, Maruyama elicited both inspiration and criticism from across the ideological spectrum.

Introduction

Maruyama Masao described himself as a "man with no talent other than scholarship" (quoted in Tsuzuki, 2013: p. 76) whose 'main business' was the study of East Asian, especially Japanese, political thought. On that basis alone, he would number among the most influential Japanese historians of the twentieth century. But the history he lived had also compelled him to open what he called a 'night stall' as a political scientist, activist intellectual, and perhaps the preeminent imaginer of democracy in Japan since 1945. Characterized variously as a modernist, national democrat, or simply as a liberal, Maruyama belonged to no party. As an opinion leader he formed an 'invisible school,' or 'spiritual community' with generations of readers (Tsuzuki, 2013: p. 236), eliciting both inspiration and criticism from across the ideological spectrum.

Maruyama through 1945

Maruyama Masao was born in Osaka in 1914. His father, Maruyama Kanji, was a prominent journalist with the Osaka *Asahi* and *Mainichi* newspapers, an admirer of British institutions, and a critic both of the political domination by the 'Satsuma–Chōshū clique' and abuse by the military of its protected position under the Meiji Constitution of 1889. The Maruyama household was frequented by Hasegawa Nyozekan (1875–1969), whose sharp critiques of the 'metaphysical view of the state' were widely read. On his mother's side – she was herself a devout Buddhist – Maruyama's family included Inoue Kiroku, a journalist associated with the nationalist Seikyōsha group. In 1921, at the age of 7, Maruyama moved with his family to the Yotsuya district of Tokyo, and one of his first compositions was an account of the Kanto earthquake of 1923 that destroyed much of the city. The era's liberal atmosphere, in short, was an element of personal and family experience – as was an undercurrent of social and political volatility.

Maruyama was educated at the apex of the imperial system: at First Higher School (1931–34), then as an undergraduate (1934–37), and finally as a graduate assistant (1937–40) in the Law Faculty of Tokyo Imperial University. He would go on to hold the position of assistant professor (1940–50) and professor (1950–71) in that faculty.

At university, Maruyama studied with Nanbara Shigeru (1889–1974), a historian of Western political philosophy. The encounter was triply significant. With Nanbara, Maruyama read Hegel, and (despite his mentor's criticisms) was himself 'Hegelianized.' Through Nanbara, Maruyama seems to have absorbed the ethos of Uchimura Kanzō's Mukyōkai, the anti-institutionalist Non-Church wing of Japanese Protestantism. Maruyama's insistence on the inviolability of conscience and physical personhood, rejection of patriarchalism, and discomfort with 'master–disciple' relations in scholarship reflect Mukyōkai concerns. Most decisively, Nanbara pressed Maruyama not to follow him into the study of Western political thought, but to engage Japan's Tokugawa legacy from the viewpoint of Western social science.

This confrontation marked Maruyama's – somewhat countercyclical – passage to intellectual maturity. He had internalized the perspectives of the so-called Lectures Faction of Japanese Marxism, which emphasized the persistence of 'semifeudalism' in Japanese society and called for the completion of the 'bourgeois revolution' that the Meiji Restoration had begun. But his reading of the German neo-Kantians (already considered passé) convinced him that Marxist historians were insufficiently conscious of the critical principles that structured their narratives, tending instead to dissolve their judgments – as to 'progress,' 'reaction,' 'stasis,' etc. – into the events themselves.

Still, Maruyama had become a historian in a Hegelian mode. History moved through evolutionary stages, in a discernible direction. But it was also 'cunning': the meaning of history, including that of his own society, had to be wrested from events through methodologically informed intellectual struggle. Neither Japanese tradition nor its Marxist antagonists provided a satisfactory method of analysis.

Karl Mannheim's *Ideology and Utopia* (1936) brought a crucial breakthrough. Here Maruyama encountered the idea of a conditioned 'mode of thought' that could be shared by even sharply antagonistic intellectual groupings; this freed him from narrowly biographical or genealogical approaches to intellectual history. Along with it came the idea of 'frames of reference' through which social groups apprehended and gave meaning to reality: the 'Five Relations' of Confucianism were a cardinal example. As with Marxists, Mannheim held that in concert with shifts in the social base, these frames of reference

also shift. But change, he stressed, was not real until it had been apprehended via a frame of reference. Not the Marxian base but the totality of social life and thought made up reality.

Of signal importance was Mannheim's insight into movements of 'return,' which was a major theme both in mid-Tokugawa thought and in Maruyama's own day. In such movements, a group of intellectuals who have begun to be 'cast up by the social process' of emerging modernity "takes refuge in the past and attempts to find there an epoch or society in which an extinct form of reality-transcendence dominated the world, and through this romantic reconstruction … seeks to spiritualize the present" (Mannheim, 1936: p. 259). Maruyama was able to see that Tokugawa movements of 'return,' particularly Motoori Norinaga's nativism (*kokugaku*), depended upon categories and modes of thought that had ostensibly been 'overcome' – in this case the sinophile Ancient Learning of Ogyū Sorai (Maruyama, 1978: p. 18). In this way, such movements provided a vital insight into how social groups thought through the great transition, via absolutism, from feudal to modern society. Underlying Maruyama's strong response to Mannheim was a shared value position. To think through the transition from feudalism to modernity, for Mannheim, was to wrestle with the democratization of society and thought. And although 'democratization' does not appear as the explicit concern of Maruyama's work until after 1945, it is hard to read even his early writings except in such terms.

Thus, even as Japan plunged into total war, Maruyama defined his position as the conscious, and again countercyclical, affirmation of modernity in the face of powerful tendencies in Japanese thought and politics that were bent on rejecting or 'overcoming' it. Modernity denoted a mode of thought marked by the irreducible difference between what is and what ought to be. This consciousness of difference, and of necessary tension, gave Maruyama a critical stance flexible enough both to resist the emotional undertow of 'national polity' thought (which identified Japan with the 'unbroken' tradition of imperial rule) and to engage Marxism as an intellectual system. This 'interiority' or self-possession formed the normative core of Maruyama's notion of subjectivity (*shutaisei*). To be modern was, in short, to exercise a transcendent, universal critical faculty in a particular social/national totality. A modern or 'open' society, in turn, was one where the free and untrammeled association of individuals sets the norm, where politics was the space in which conflict was confronted and resolved in an ongoing history (as Hegel put it) of 'progress in the consciousness of freedom.' Human society and institutions, therefore, were neither natural nor metaphysically guaranteed. Rather, they were vital fictions worked out by actors with some degree of self-consciousness. The modern consciousness did not contrast fiction to reality or truth, but rather negated any metaphysically guaranteed order in which norm and nature, the cosmic and human spheres, mirrored and confirmed one another.

Here we recognize the core argument of Maruyama's first major work, *Studies in the Intellectual History of Tokugawa Japan*. Written and published separately in the *Kokka Gakkai Zasshi* between 1940 and 1944, and completed literally moments before his departure for military service, they appeared as a book in 1952. Maruyama had provided for Tokugawa intellectual history a narrative of the breakup of the neo-Confucian, 'natural order' orthodoxy of Zhu Xi under the external pressure of social and economic contradictions and the internal dissolution of its 'continuative mode of thought.' The negation of orthodoxy came in the form of Ogyū Sorai's paradoxical 'logic of invention.' Sorai as a Machiavelli–Hobbes *manqué* had called upon the shogun Yoshimune to 'reinvent' along pristine feudal lines a rapidly commercializing social order, thus seeking to 'produce nature' by the absolutist 'logic of invention.' "In order to solve the crisis of feudal society, Sorai set out to destroy the theory of natural order, but instead brought forth a demon whose actions he was unable to control" (Maruyama, 1974: pp. 222, 238). To have discovered in Sorai an 'autonomous personality' and a 'discoverer of politics,' and to have shown that "even the most monolithic of systems contains within it the inherent necessity for its own collapse" represented nothing less, Maruyama declared, than "the salvation of my soul" (Maruyama, 1952: p. 8).

Yet the 'demon' of this inventive logic was destined to be frustrated. Japanese history, then and thereafter, appeared to Maruyama as a succession of thwarted breakthroughs to universality. Japan could have, but did not, become a fully modern, democratic nation-state. "The degree to which the European [*Yōroppateki naru mono*] makes its way into the realm of the spirit," he wrote in 1943, "provides a barometer for gauging the total phenomenon of Japanese modernization." By this measure, Japan after the Meiji Restoration had assimilated the material techniques of the West, but had yet to undergo a spiritual revolution. Politically, the potentially liberating 'logic of invention' had been short-circuited into a ruthlessly pragmatic *raison d'état* and trapped, so to speak, in institutions of state closed to public scrutiny. In society as a whole, the senses had been liberated, but the nation had yet truly to confront the 'European spirit,' and instead persisted in treating European thought as a fetish. Japan's intellectual world had therefore developed – Maruyama quotes the émigré philosopher Karl Löwith – into a 'two story house' with no staircase to connect the floors (Maruyama, [1943]1976: pp. 119, 127–132). As yet, Maruyama wrote, at the first sign of absorption, all the trappings of Western thought and culture could simply be shaken off. But he believed this to be a deeply embedded fallacy, one that had led 'spiritual' Japan to embark on a catastrophic attempt to purge itself and Asia of 'materialism.' Far from claiming that Japan was called to 'overcome' modernity, Maruyama believed that modernity, as a conscious participation by individuals in the struggle, on the social plane, of 'ought' with 'is,' constituted a 'not yet' to be struggled for.

It certainly appears that in his work up to 1945, Maruyama was idealizing the West and denigrating Japan for its historical failures and 'lack' of a true Western consciousness. Understandably, this criticism followed him for most of his professional life. As Maruyama himself remarked some years later:

> If I am told, "You're idealizing the European past and treating it as universal," I can only answer: That is exactly the case. This isn't because there are no universal elements in other cultures, of course. But I acknowledge that in my thinking I rely on abstractions from European culture. I consider it to be a universal legacy to humankind [*jinrui fuhen no isan*]. I firmly believe this. And I want more and more to study it.
>
> Maruyama and Tsurumi, 1969: p. 93

Maruyama's strong affirmation of the universality within European culture came at a time in Japan when an already myopic and defensive exceptionalism had taken its most brutal form; clearly his confrontation with this exceptionalism marked his life in profound ways. Moreover one cannot read Maruyama in context without sensing an overriding critical and national concern. His work, in other words, was nationalist in intent: hence his lifelong attraction to Fukuzawa Yukichi (1835–1901), the great publicist and prophet of Japan's nineteenth century modernization. But as it was for Fukuzawa, for Maruyama too this nationalism was meant to be relative, not solipsistic – nationalism as a freely elected affinity and for that reason an instrument of genuine universalization.

Maruyama after 1945

At War's end, Maruyama was stationed in Hiroshima, attached to an army unit that monitored shipping in Japanese waters; his mother died on the day of Japan's surrender. Intellectually, he emerged from the War as a 'protestant': he had written in covert protest of an unfree present, and continued thereafter to be concerned with overcoming obstacles to freedom and modernity in Japan. It was the typical claim, and the central problem, of his 'protestantism' that such obstacles lie most thickly on the ground of Japanese tradition itself. In this sense he was, as many have described him, a modernist without apology.

With Japan under occupation, Maruyama struggled to adjust to the tragicomic feeling of having to "learn the ABCs of modern civilization from General Douglas MacArthur" (Maruyama, [1945]1976: p. 188). Yet more than anything else, this was liberation, albeit unearned. Now was the time to place the language of conscious, engaged, mass democratic action at the center of Japan's political discourse. In this effort, the institutional, intellectual, rhetorical, and psychological dimensions of Maruyama's public work were related – as was true for anyone active at the time – with unprecedented dynamism.

Negation was the first task. The assignment of 'war responsibility' required more than an attack on the 'military cliques' or *zaibatsu*. To expose the social roots of war, it was necessary to destroy the *ancien régime* in the domain of thought and ideology, above all the "tenacious familial [*dōzokudanteki*] social structure and its ideology, which is the hothouse of the old nationalism" (Maruyama, [1951]1969: p. 152; Maruyama, 1966: p. 168). Never had Maruyama felt so vindicated as by this opportunity for public expression: as a student at First Higher he had been arrested, jailed, beaten, deprived of personal papers, and placed under surveillance for attending a legal gathering of the Society for the Study of Materialism. It was an experience that left him in tears of chagrin at his inability to utter one word of protest. The Peace Preservation Law of which he had run afoul symbolized to him the legal paranoia of the *tennōsei* or 'emperor system,' and now the entire apparatus was being exposed to public scrutiny.

With the publication, in the new opinion journal *Sekai*, of 'Theory and Psychology of Ultranationalism'('Chōkokkashugi no ronri to shinri') in May 1946, Maruyama appeared – 'like a comet,' as the formula had it – to illuminate the devastated intellectual landscape. His attempt to render visible the "invisible net" of *tennōsei* ideology was "as influential as it is possible for a printed work to be" (Tsuzuki, 2013: p. 114), and it seems to have had a virtually physical impact on readers. To begin with, Maruyama's description of 'power dwarfing' (*kenryoku no waishōka*) captured a salient aspect of the public posture of key civilian and military elites, who habitually minimized their personal responsibility while emphasizing their lofty position of proximity to the source of ultimate value. It was their very closeness to the emperor that granted them the privilege of being dwarfed. Also penetrating were the observations concerning the 'transfer of oppression,' which recalled the common experience of many Japanese who found themselves projecting outward and downward the recurring sense of anger and violation that was inseparable from the workings of imperial Japan's familistic hierarchy.

Most important was Maruyama's jarring insight into the 'exteriorization of morality' and its consequences: the 'pathological' identification of the petty self with expansive state power, and along with it the severely compromised capacity to resist authority, or to live according to a moral standard internal to the personality. In this feature of the imperial state, the fact that it "trampled with shod feet on the mind [*seishin*] of every single person" (Maruyama, [1979]1995: vol. 11, p. 150). Maruyama saw the core of 'ultra' nationalism, and its decisive difference from the 'neutral' stance ostensibly assumed by the states of the West concerning moral values. The entire structure of the argument (juxtaposing an actual Japan to an ideal or abstracted West) may seem problematic today. The essay's power derived from the fact that Maruyama was writing of truly public matters, of the common experience of his countrymen. Everyone 'knew' what he was saying; he was trying to provide not merely description but concepts for the analysis of this experience. In this sense, Maruyama's essay opened a new phase in public and social science discourse, and in short order was followed up by major analyses of Japan's wartime leadership, the career of fascism in Japan and the contemporary world, and the theoretical background and prospects of Japanese nationalism (see Maruyama, 1966).

Thus far negation: but what did Maruyama seek thereby to construct, to affirm? The answer could now be stated openly: democracy. Despite the powerful presence of 'America' as occupier and as a model state and society, however, it was increasingly clear that democracy could not be imposed satisfactorily from without. Writing in the bitter aftermath of MacArthur's banning of the 1947 general strike, Maruyama defined the task as follows:

> It has now been made our task to accomplish what the Meiji restoration was unable to carry through: that of completing the democratic revolution. We are being pressed to confront the problem of human freedom itself. The situation facing Japan, of course, is not such that it can be resolved simply by rejoining the orthodox lineage of modern freedom. The bearer of "freedom" is no longer the "citizen" as conceived by liberals since the time of Locke; but must rather be the broad working masses with workers and farmers at the core. Even then the issue is not merely the sensual liberation of the masses, but rather how and how thoroughly the masses are to acquire a new normative consciousness.
>
> Maruyama, [1947]1976: p. 305

Clearly, Maruyama was a self-conscious heir of the European, and Meiji, enlightenment. For the most part he addressed his educated audiences through media of limited reach – university and public lectures, appearances before community and educational organizations, publication in opinion journals rather than mass-circulation dailies, etc. Although he was involved in typical 'enlightenment' projects such as Kibe Tatsuji's Shomin Daigaku ('People's University'), Maruyama's professional identity remained closely tied to Tokyo University, where he held the chair in East Asian political thought until his retirement in 1971. His organizational commitments were also small-scale. After 1945 he joined a number of groups, among them the Seinen Bunka Kaigi (Youth Culture Conference), Nijusseiki Kenkyūjo (Twentieth Century Research Institute), Shisō no Kagaku Kenkyūkai (Institute for the Science of Thought), Kenpō Mondai Chōsakai (Constitutional Problems Survey Group), Heiwa Mondai Danwakai (Peace Problems Discussion Group), and so on. Some of these memberships lapsed quickly; others were kept up. Maruyama never became a party ideologue of any kind on a national level, remaining instead an independent member of the left.

Maruyama, in short, relied implicitly on the diffusion and 'translation' of his ideas into the workaday world via a greatly expanding student and white-collar stratum. Indeed, he had come to recognize that enlightenment by and for the academically pedigreed could only go so far in rooting democracy. This was above all to be an age of the masses, of organized capital and labor – including mental labor. As was the case for the entire Japanese, left throughout the 1950s, for Maruyama too the relation of democracy to socialism – the issue of revolution – became a pressing issue.

Underlying the question of any political commitment, however, was the intellectual (and moral) problem of 'attitude determination.' Maruyama could not embrace the notion of 'class subjectivity' championed in the late 1940s by Marxists such as Umemoto Katsumi. This threatened to degenerate into formalism: the 'party of the proletariat' could not presume to define a 'new normative consciousness.' Ill at ease with such formalism, and contemptuous of wartime 'apostates' who had now returned aggressively to the leftist fold, Maruyama initially refused direct political engagement. Although he rejected as elitist and reactionary the 'old' Japanese liberalism, which had been uncomfortable with any notion of mass politics, class – or social – conflict, Maruyama's political commitments immediately after 1945 were 'diagonal' at best.

The incarnation of the Cold War in Japan, however, forced him into a higher-profile stance. In 1950, self-proclaimed 'realists,' including the Tokyo University historian Hayashi Kentarō, called for Japanese intellectuals to choose sides in the ideological struggle against communism, and in support of a bilateral rather than comprehensive peace treaty. Maruyama demurred. He did so for a number of philosophical and practical reasons, which he expressed in his open 'Letter to a Certain Liberal' (Aru jiyūshugisha e no tegami; Maruyama, [1950]1966).

First, it ran against the grain of Maruyama's self-described 'high-level pragmatism' to be compelled by external forces to subscribe to the rigid metaphysics of Cold War theology. By doing so, one precluded in principle the formation of political positions that would respond to, and help define, the objective demands of a given situation. He refused the 'liberal's' demand that he foreswear any support to the communist party, newly chastened by Cominform's criticism and reeling from the so-called Red Purge. We need, he said, to recognize the "paradox that the establishment of the autonomous human person moves forward via the energy provided by *groups* that, in comparison with Western societies, *stand relatively speaking on the left*" (Maruyama, [1950]1966: p. 513). Maruyama would aid those tendencies that promoted the modernization of Japanese society, and oppose those that did not.

Japan's 1950s, in fact, brought a decade of serious and consequential conflict over the politics of modernization. Along with Shimizu Ikutarō, Maruyama was recognized as an intellectual godfather of the national movement against continuation of the US-Japan Security Treaty (ANPO) that ushered in the end of that decade. In the ANPO protests, Maruyama saw an engaged public – students, white-collar workers, housewives – embodying the ideals of democratic subjectivity he had sought to translate to the Japanese body politic. It does appear that the 'new normative consciousness' he had called for in 1947 had taken hold:

> How do we conceive of politics?… It's a matter of habit, of seeing politics as activity that, even if it makes up only a small part of what we do, day in and day out, still occupies that place *consistently*, as part of carrying out the commonest of our social obligations. More so than any other ideology, however magnificent, or any system, however formally equipped it may be, democracy depends on this kind of thinking. This is its true foundation. Here in Japan we may have lacked the tradition of direct democracy practiced in the Greek city-states. But instead we have as our intellectual heritage the splendid concept of "homespun [lay] Buddhism." Put in contemporary terms, this means the political activity of non-professional politicians. You don't have to "take the political tonsure" in order to get involved in politics. When politics is left to politicians and Dietmen—people whose purpose is politics per se, or to groups such as parties who approach it in the same way—from that moment democracy begins to die.
>
> Maruyama, [1960]1966: p. 182

The 1960 protest against the continuation of (a revised) ANPO was in part bruising political struggle, in part collective effervescence. One of its legacies was undoubtedly the birth of the 'citizen' – a part-time politician out of necessity – as a force in Japanese politics. But while the movement brought down the government of the arch-technocrat and inveterate anti-communist Kishi Nobusuke, it failed in its chief aim. Together with the defeat of union-led strikes at the Miike coal mines, the ANPO struggles paved the way for a successful 'economistic' settlement that in effect redefined Japanese democracy. The institutional framework laid out in the new constitution remained, along with the democratic rhetoric of that period. But under a deepening conservative hegemony, its practical core would no longer be formed by social mobilization and broad political criticism. Instead, it entailed consumer participation in an expanding economy driven by "large-scale mergers and the development of designated contracting systems" (Ishida, 1984: p. 198). The anti-Treaty demonstrations looked to be an exceptional, albeit vital episode, while the meaning of the postwar 'enlightenment' grew clouded.

The Problem of 'Japanese Thought'

Maruyama's key text from these years is *Japanese Thought* (*Nihon no shisō*, 1961). Consisting of essays written between 1957 and 1959, it seems to prefigure the ambiguities of the entire ANPO experience, giving full vent to the agonistic strain in Maruyama's thought yet revealing nuances not present in his immediate postwar writings.

The essence of Japanese thought, Maruyama argues, is to have no essence. Japanese tradition has no axis analogous to Christianity in the West, or Confucianism in China. It is a tradition without structure in which history becomes the nostalgic welling up of national memory, something "akin to the attachment felt by a mother toward a child she has lost" (Nakajima, 1968: p. 84). Yet the intellectual landscape is far from empty. Japanese thinkers have accumulated an extraordinary 'stock' of discrete ideas to draw on for their own purposes. What is lacking is an "absolute being or a 'Way' that logically and normatively orders the world in its own characteristic manner." In its absence, Maruyama argues, 'Japanese thought' formed a tenacious pattern by which 'faith in felt reality' (*jikkan shinkō*) and 'faith in theory' (*riron shinkō*) operated as functional equivalents, cutting off the dialectic of mutual negation, testing, or correction that Maruyama, from his transcendent position, finds to be essential to the 'normal' operations of the socialized intellect.

Maruyama was not principally concerned with accounting for the origins of Japan's nonaxiality. He begins *in medias res*, looking back across the great but not far distant rupture of 1945. How did 'tradition,' as mobilized under the modern emperor system, actually function? In the wake of defeat, Maruyama would have answered that it functioned in a uniformly oppressive manner. By the time of *Nihon no shisō*, he has softened considerably his attitude toward 'tradition,' which he discusses in terms of an ethic of 'being' versus 'doing.' Now, rather than call for the elimination of the ethic of 'being,' he urges its incorporation in a synthesis of traditional and modern styles of life and thought. Echoing Max Weber, Maruyama finds that 'being' is functional in the sphere of art and culture: indeed it stands in immediate need of protection from an obsessive 'modern' concern with producing results. As he observed elsewhere, "*The Tale of Genji*, *Hamlet*, and *Faust* cannot be shot off as rockets" (Maruyama, 1969: p. 310). At the same time, he finds Japanese society lacking in a political ethic of 'doing,' where results – the rationalization of means according to publicly determined ends – do indeed matter. By applying criteria of instrumental rationality where they did not belong, Japan had become hypermodern in one sphere, and insufficiently modern in another.

But how does this relate to 'Japanese thought'? The answer lies in the totality of elements, premodern, modern, and hypermodern, and their particular distribution or valences within the social system; it is in the whole, rather than in any of its parts, that the Japanese mode of thought operates. And as Maruyama shows, there are definable historical patterns to this operation, which now can, and must, be challenged. The ideology of *kokutai* – the unbroken line of imperial rule over Japan – had legitimated rapid institutional modernization in the name of the monarch. At the same time, it claimed that the monarchy was the supreme embodiment and validator of the entire system of patriarchal, factional, and personalistic human relationships that characterized village society. The 'emperor system' in this sense was the most powerful and consequential 'invented' tradition of modern Japan. It provided the institutional and linguistic frame through which all other 'inventions' received their official imprimatur. The task now was to differentiate, to overcome the deep-seated 'need' for the all-encompassing legitimating frame that was at once so comforting and suffocating. But could Japanese people live without it? Could they overcome 'Japanese thought'? Maruyama was uncertain. In an enduring metaphor, he noted the tendency of organizations of all kinds in Japan to form themselves into 'octopus pots' (*takotsubo*) in which the group's activities, ideas, and values become largely self-referential, the authority of the group self-justifying, and socially isolating. This includes 'modern' organizations – political, business, and technical as well. Parallel to this is the increasing sophistication, centralization, uniformity, and pervasiveness of the mass media. The result of their interaction is a society in which lateral ties between groups of all kinds are weak; groups form images of themselves and the 'world' that go unchallenged and 'walk on their own.' In the absence of such ties and of genuine feedback throughout society, critical and democratic consciousness is fragmented and blunted. It is precisely in this mix of hypermodernity in one sector with premodernity in another that Maruyama saw functional continuity with *tennōsei*, albeit sans *tennō* in the prewar mode.

Counterposed to the 'octopus pot' was the *sasara*, a bamboo whisk, with a shared base that is finely separated toward the tip. The finely separated tip connotes articulation, differentiation, specialization, and pluralism as a value. But how is the 'shared base' of the *sasara* to be understood? Does it refer to a single nation or ethnicity with an intuited cultural code? It would seem not. Speaking of the development of the European social sciences, Maruyama refers almost enviously to a 'long common tradition' linking Greece, the middle ages, and the Renaissance with the modern emergence of highly specialized disciplines; the comprehensive systems (or at least catholic concerns) of 'Hegel, Stein, and Marx, or Bentham and Comte' that were typical of the early nineteenth century give way by its end to the specialized sciences familiar today. It was these latter – the 'finely separated tips' of the *sasara* – that had been cut off from their roots and transplanted to Japan. The shared root, in other words, was a history of dialectic, argument, and contestation. Without this history, the disciplines of social science in Japan were 'academic' from the beginning, and even more susceptible than in Europe to self-enclosure. More fatefully, the 'academy' itself was presumed to exist for the service of a state-defined public good.

Nihon no shisō, Maruyama asserts, is also his own 'self-criticism' from the point of view of "radical intellectual aristocratism [*kizokushugi*] linked interiorly with a radical democracy": he looks forward to a *sasara*-type society, one in which the image of 'Karl Marx reading Hölderlin' would capture the intellectual life of its people (Maruyama, 1961: pp. 179–80). For all that it seems to set out an uncompromising task of mental revolution, and therefore remain true to agonistic modernism, *Nihon no shisō* is good-natured and surprisingly upbeat in tone. It points to a modernism in process of differentiation, one making its peace, via the categories of aesthetics – including linguistic play – with nationality. But

would that be a slippery slope? Would modernism come to valorize its moment as one of modernity achieved, pressing forward to the presentation of Japan as a new model of development? Or would modernism retain the capacity for 'utopian' resistance to the status quo, even at the risk of marginalization? What, in short, would be the intellectual consequences for Japan's democracy of coming to terms with nationality?

The balance, Maruyama seems to have feared, was tipping in favor of the 'octopus pot' rather than the 'bamboo whisk.' More and more, Japanese society lacked the 'feedback of counter communication from the periphery,' without which it would corrupt (Maruyama, 1969: p. 347). Yet he had little to say about the concrete identity of the 'periphery,' the content, or social character of the feedback it generated. Indeed he appeared to pin his hopes on intellectual migrants to the periphery as producers of that vital 'counter communication.' Perhaps that should not be surprising. Maruyama's image of Japan's 'periphery' was one of traditionalism and irrational attachments. Although he had argued that democracy had to become 'irrationalized' – or deintellectualized – this still left unanswered the question of how the center is to be 'reintellectualized' from below. And because a backward and traditionalistic periphery was, in effect, a structural requirement of his thinking, Maruyama could never answer such a question.

Maruyama, then, remained a protestant. For him, democracy was priesthood of all believers, a 'permanent revolution.' Its enemy was complacency or 'blind faith' in ideology or institutions. No value, freedom (or democracy) included, could be made 'real' simply by being divested of utopian elements. 'Realism' as the ideological affirmation of the status quo, and the identification of the established order with democracy as such, in effect killed democracy in its own name. Thus Maruyama answered a nationalist critic of postwar Japan's 'occupation' or 'sham' democracy: "As for my own choice in the matter: Rather than opt for the 'reality' of the empire of Japan, I'll put my money on the 'sham' of postwar democracy" (Maruyama, 1966: p. 585). But who was betting along with him?

Shifting Ground: The Later Maruyama

The major writings of Maruyama's later years – 'later' beginning piecemeal by the late 1950s and definitively so by the early 1970s – were almost entirely historical. Increasingly he explored the problem of 'continuity in change' in Japanese political, ethical, and historical consciousness, using the metaphors, successively, of 'prototype,' 'ancient substrate,' and 'basso ostinato' as he refined his description of how they worked. Much as the seminal ethnographer Yanagita Kunio pursued the original Japanese ever outward to the archipelagic periphery, Maruyama pushed the sources of 'Japanese thought' further and further back in time. "A century after Nietzsche babbled about the death of God," Maruyama observed, in its absolutization of the 'now,' Western historicism had in fact drawn strikingly close to the Japanese scene. "It may be," he wrote, "that the 'continuity in change' that distinguishes our historical consciousness has, in *that aspect* as well, been a factor in placing Japan at the forefront of world's most advanced countries. Should we regard this paradox as yet another instance of 'the cunning of reason,' or as a comedy that is rapidly approaching its conclusion?" (Maruyama, 1972: p. 41).

For those who recalled his Mannheimian early work and acute analyses of political psychology, the later Maruyama was disappointing: ahistorical and essentialist. Yet it seems clear that he wished to hasten the 'comedy's' end, even if at the price of intellectual uncertainty and anxiety. The forms of political, historical, and ethical consciousness that he came to discuss in terms of sudden 'welling up' from the historical (not social) depths, or of a submerged musical line breaking through as the dominant 'theme,' are no more than the reverse of the forms of political subjectivity that he hoped would emerge from, and promote, the process of democratic revolution in postwar Japan. It was the 'universal' that gave meaning to the 'particular,' movement to stasis, and utopia to 'reality.'

In the end, Maruyama Masao was a thinker of the democratic nation-state and, increasingly, of a unitary, intransigent culture that tormented him intellectually. At the level of conceptualization he was unquestionably 'complicit' in both, thinking through and against the nation-state, through and against the national culture. What does 'complicity' mean? It is a major problem today and a theme of much recent criticism – including postcolonial criticism of Maruyama. As Fred Dallmayr has noted, in our times opposition to the ostensibly genetic (biology, race, and nature) has required a dualism whose other antipode is 'spirit.' The options for or against spirit, for or against a metaphysics of subjectivity, are "all 'frightfully impure and contaminated.' One always has to ask oneself which option or 'type of complicity' is less grievous" (Dallmayr, 1993: pp. 35–36). Maruyama sought to contest the sway of 'nature' over 'nation,' to free it for the 'spirit' he called democracy. He had a lively capacity for concrete analysis that he applied to the pathologies of revolution and counterrevolution – phenomena, that is, of repressive and mobilized political essentialism. But he was not a postmodern thinker; he retained in his thought the constitutive dualism of subject to object and the belief, shared with Harold Laski, that within the framework of a revolutionized polity the 'best self' of each individual could be brought to realization. In this or that aspect – such as his notion of revolution as massive (and rare) value dissensus – one can certainly find hints of a Foucaultian perspective. But it is with hints that he stops. Perhaps Maruyama did not push deeply enough in considering the problems – the pathologies – of 'normal' modernity itself. The question now, however, is how the inevitable problem of complicity is to be faced by those who would place themselves beyond the horizon of the modern.

Marx, Karl (1818–83)

Abstract

Karl Marx (1818–83) developed a distinctive 'new materialism' through which human history was understood as a succession of economic modes of production on which legal, political, moral, and intellectual systems were dependent, rather than the reverse. Science (*Wissenschaft*) was thus a practical activity undertaken in circumstances that were necessarily historical and social, presuming the ubiquity of class struggles and the communist project to transcend them. Marxism, originating with his friend and sometime collaborator Friedrich Engels (1820–95), promoted the controversial summarization of Marx's work in terms of a 'materialist conception' of history founded on 'dialectical' laws of nature, history, and thought.

For Marx science (*Wissenschaft*) (Terms denoting a unified conception of the sciences derived from the natural philosophy tradition and promoted by the German idealist and Hegelian philosophies. Marx's 'new materialist' version of this was opposed to empiricist reductionism of knowledge and truth to ahistorical and individualistic accounts of perception. His 'outlook' presumed that knowledge of any kind is practical, social, historical, and political in origins and usage.) was itself a unity, and natural science was an activity within, rather than a model for, the human social world. For him the master science was political economy because it dealt with the way that industry and technology had transformed humanity. His lifetime project was a critique of that science, informed by his understanding of communism (term denoting a long tradition which emphasizes community-sharing of goods and services, and other cooperative strategies in social relationships, to minimize conflict and corruption in society; Marx, Engels, and others revived this in the early to mid-nineteenth century to democratize not only political institutions but also the economic structures and practices through which goods and service are produced and consumed using modern industrial means) as the political movement to emancipate the working class. Friedrich Engels (1820–95), V.I. Lenin (1870–1924), and other commentators ascribed to Marx the discovery of important scientific laws of human history and capitalist production, attributed to him a unique 'dialectical' scientific method, and promulgated a 'scientific socialism' (term coined by Engels to summarize Marx's 'new materialism' as a union of anticapitalist but proindustrial politics, founded on a 'dialectical' science derived from both Hegelian logical reasoning and the factual character of the physical sciences) in his name. The extent to which posthumous 'materialisms' in social and natural science were an accurate reflection of Marx's own views has been debated within and outside the Marxist tradition, and these debates have contributed importantly to the philosophy of science. Marx and Marxism (term not commonly used until the 1880s and 1890s after the widespread circulation of Engels's summarizations of Marx's 'outlook' as a 'materialist conception' of history founded on 'dialectical laws' of nature, history, and thought; as a philosophical, political, and social scientific movement it was essentially contested, and by the early 1900s it had sparked a doctrinal conflict between orthodox and 'revisionist' versions) have themselves been reinterpreted separately and together in the light of later developments in twentieth- and twenty-first-century philosophies of science and social science. In empirical terms almost any social scientific study of social class in the context of industrial, 'emerging,' or developing economies and societies owes an important debt to Marx's emphasis on the social and political consequences of class struggle. (Term denoting a distinctive consequence of Marx's 'new materialism' through which human history was understood as a succession of economic modes of production. From this perspective social gradations were importantly coincident with a division of society into 'haves' and 'have-nots' – those who benefited disproportionately from surpluses and luxuries, and those who worked to produce these things, but were denied access to them. This was because of social, political, legal, religious, or other structures of oppression, against which there was persistent but more or less 'veiled' civil war of resistance. Marx and Engels predicted that a communist and specifically proletarian or industrial workers' revolutionary victory would institute a new and classless social and political order.)

Marx was hailed at his death as a 'man of science' who had made two great discoveries in but one lifetime: 'the law of development of human history' and 'the special law of motion governing the present-day capitalist mode of production' (Engels, 1989: pp. 467–468). In this graveside eulogy Marx's longtime friend and sometime coauthor Engels likened the first of these great discoveries, previously christened 'the materialist interpretation of history' (term coined by Engels to summarize Marx's 'conception' of history as one of successive economic 'modes of production' and concomitant class struggles to be transcended by a communist social revolution utilizing the productive powers of modern industry. Its relationship to social science has been controversial throughout the twentieth-century and remains so today) (Engels, 1980: p. 470), to the formulation by Charles Darwin (1809–82) of 'the law of development of organic nature' (Engels, 1989: p. 467). In other overviews of Marx's work, Engels linked Marx's critical work on political economy and capitalist society with a dialectical method in science derived, so he said, from the philosophy of G.W.F. Hegel (1770–1831). Engels wrote that "Marx was … the only one who could undertake the work of extracting from the Hegelian logic the kernel which comprises Hegel's real discoveries" (Engels, 1980: pp. 474–475). Moreover for Engels,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61088-7

science as conceived by Marx was fully compatible with, and indeed an integral part of, a revolutionary political outlook and practice: "Science was for Marx a historically dynamic, revolutionary force. … His real mission in life was to contribute, in one way or another, to the overthrow of capitalist society" (Engels, 1980: p. 475).

Famously Marx himself denied that he was a 'Marxist' (Engels, 1992: p. 356), whatever that may have meant to himself, and to his friends and enemies while he was alive. While the origins of Marxism lie in Engels's accounts of Marx's life and works from 1859 onward, and in Marx's own published works and articles, Marxism as a science and as a political movement dates from the years after Marx's death in 1883. For over a century it has been an intellectual and political force to be reckoned with, though the initial presumption of methodological and doctrinal unity, implied in the reference to an origin in one man and his works, inevitably began to break down. On both the intellectual and political fronts, the current age is one of post-Marxism.

In another influential overview of Marx's intellectual career, Lenin suggested that Marx combined German philosophy, English political economy, and French socialism and revolutionary doctrines in a unique way (Lenin, 1964: p. 50). Most intellectual biographies proceed chronologically and thematically through this list. However, in setting out what distinguishes Marx as a social scientist, and what contributions Marxism has made to social science, it is more productive to take the direct approach and to outline the characteristics of the Marxian synthesis. This will necessitate some contextual discussion of what science and philosophy meant in Marx's time and milieu, and what sort of political strategies and actions were possible for a committed socialist when even constitutional politics was radical and subversive.

Science and Philosophy

Marx was born on 5 May 1818 in Trier in the Rhineland. His family were converted or at least nonpracticing Jews, and he had a classical and liberal education. This took him to the faculties of law and philosophy at Bonn and Berlin universities in the mid-1830s to the early 1840s, preparing him, rather inadvertently, for a career as a progressive journalist and political radical. This was a time of political reaction in the German states when liberals, especially students, resisted the authoritarian doctrines and practices of self-styled autocrats. Liberals argued instead for representative and responsible government that would protect individual rights to free expression and institute a socioeconomic system favorable to individual mobility. While this may sound familiar enough to present-day readers, the political dialogue of Marx's time now seems laden with obscure philosophical and religious issues. This was partly the result of heavy government censorship imposed on overtly political pronouncements, and partly the result of the requirements of the debate: what facts and arguments would sustain a doctrine of popular sovereignty against the reigning doctrines of absolutist rule by divine right?

The Hegelian idealist philosophy within which these coded political debates took place was itself controversial in relation to the Trinitarian truths of the Christian confession, and this had indeed been recently and notoriously explored by the historian D.F. Strauss (1808–74) in his *Life of Jesus* (1835), and by the philosopher Ludwig Feuerbach (1804–72) in his *Essence of Christianity* (1841, 2nd edn., 1843). Marx was swift to draw the radical conclusion of atheism from these writings, and to align himself with a 'new' materialism rooted in human experience, which he defined as economically productive and historically changing. In the 1830s and 1840s, and particularly in the German-speaking world, 'science' as *Wissenschaft* referred to knowledge in the broadest sense systematically presented. Moreover the tradition of natural philosophy was central to this conception of science, which did not readily admit any great distinction in method between natural and human subjects of study. Science as *Wissenschaft* relied on scholastic concepts and commonsensical observation, rather than on mathematical abstraction and testable hypotheses.

Hegelian idealist philosophy was in any case utterly hostile to a materialist ontology of matter-in-motion and an empiricist epistemology through which truth is ascribed to concepts in so far as they coincide with human sensory experience of the material world. The later nineteenth century saw the rise of such materialist accounts of the natural sciences as empirical modes of study. Subsequently the development in the early twentieth century of the modern social and behavioral sciences was modeled on these physical scientific presuppositions and practices. In any case since the seventeenth and eighteenth centuries English-language philosophy has been hostile to philosophical idealism, and very closely aligned with philosophical empiricism. It follows that Marx's early works, and the overarching conception of science extending through his later works, can be quite difficult to understand from a later vantage point in the twenty-first century. Certainly the reader must be very careful in noting any claims in Marx about what science is supposed to be, so that his thought can be understood without anachronism.

In so far as Marx's notions of science have been influential, a conception of science rooted in idealist *Wissenschaft* has thus survived and flourished. This conception may not cover all conceptions of science within Marxism, nor is it necessarily exactly aligned with those that claim to be Hegelian in origin. Rather it is distinguished by these features:

1. a focus on human ideas as the medium through which science itself exists, rather than a view that knowledge about humanity must in some sense mirror knowledge of the physical world;
2. a presumption that throughout history the human focus on what is true and meaningful will change, rather than a presumption that truths are fixed by realities outside of human experience;
3. a view of science as a form of practical knowledge developed for, and incorporated within, a comprehensive range of human activities, rather than as a realm of abstract truth sought for its own sake by objective observers and politically neutral scientists; and
4. a political presumption that a critical evaluation of present practice, including practices of power and politics, is a necessary condition for productive science, rather than a presumption that proper science is necessarily unconcerned with its own political context, or a view that it simply does not have one worthy of notice.

Natural Science and Social Science

Marx's critique of political economy was a lifetime project pursued in political and intellectual terms that are somewhat unfamiliar today and require careful explication. His ideas and concerns surfaced in his early journalism, published in 1842 when Prussian censorship was comparatively relaxed. They can also be traced in his notebooks and articles from the following 2 years, during which time his newspaper was closed down, and as he says, he 'retired into his study.' Marx had only limited contact at this time with the social science of political economy, and in common with other German readers, he viewed writers such as Adam Smith (1723–90), Adam Ferguson (1723–1816), and Sir James Steuart (1712–80) through the medium of Hegel's synthetic and critical philosophizing on this subject, particularly in the *Philosophy of Right* (1821). This work was subjected to a lengthy critique in 1843, unpublished by Marx in his lifetime, and by 1844 he had also completed a set of 'Economic and Philosophical Manuscripts,' again largely unpublished until 1932. While there is of course controversy over the relationship between these works and those that Marx wrote later in life, there are demonstrable continuities in terms of text and project that confirm the early 1840s as the period when Marx's critique of the economic categories was truly launched.

Politically the young Marx aimed to produce a critique of political economy informed by his own version of some of the principles of socialism and communism that were then current. These were mostly French in origin, and derived from the writings of Henri Saint-Simon (1760–1825), Charles Fourier (1772–1837), and Étienne Cabet (1788–1856). Marx was also influenced by more contemporary writers such as Moses Hess (1812–75), who identified (rather hopefully) the newly emerging industrial poor as prime movers in socialist politics. At this juncture the relationship between socialism as a political doctrine, and social science as the pursuit of knowledge about society, may seem tenuous. However, in the intellectual and political context of the time the very notion that 'society' needed a scientific investigation was itself subversive and 'socialistic.' The established monarchical order was content by contrast to rely on Biblical fundamentalism, 'commonsensical' conservatism, and vigorous repression of any 'free thinking' that might stir up issues concerning social class and political power. This free thinking was exactly what both liberalism and socialism were about, and the two constituted a potent alliance at the time, albeit with many in-built tensions around social class, political participation, and economic goals.

After the revolutionary events of 1848–49 Marx went into exile in England, and during the remainder of his life, his political involvements were necessarily rather problematic in that context. As he himself noted, London was an excellent center for studying both the social science of political economy and the industrial and commercial life that it theorized. While the English tradition in political economy (actually more Scottish than English) was empiricist in its assumptions and methods (rather than idealist, as was German tradition), it was at this stage not rigorously mathematical or deductive. This paradigm shift occurred in the 1870s following the work of William Stanley Jevons (1835–82) and other pioneers of the 'marginalist' revolution.

Central to Marx's critique was the work of David Ricardo (1772–1823), whose *On the Principles of Political Economy and Taxation* (1817, 3rd edn., 1821) is classically descriptive and deductive in a mode of natural philosophy not far removed from Aristotelian conceptions. Ricardo defined and explicated the origins of wealth in terms of commercial value, relating this to the human labor involved in manufacture, and assuming the distribution of wages, profit, and rent to the 'three great classes' that necessarily constitute modern societies. Marx's critique of this influential view was both political, arguing that class-divided societies are but a transitional phenomenon, and technical, arguing that Ricardo's concept of labor could not account for the accumulation of profit through the exchange of value. This critique was published in stages, most notably *Capital*, Vol. 1, (1867) and has been subsequently enlarged with edited versions of articles for succeeding volumes and studies.

Marx died on 14 March 1883 in London of natural causes, after 35 years of exile from his native Rhenish Prussia. While other '48 ers' managed to settle their differences with the regime and to regain their civil rights, Marx made only infrequent nonpolitical visits to Germany, and was resolved to maintain his family home in England. He had married Jenny von Westphalen in 1843, and by 1855 they had three surviving daughters, having lost two sons and another daughter (Franziska) to childhood illnesses, certainly exacerbated by harsh financial circumstances. Since 1962 it has been claimed that Marx was the father of Frederick Demuth, the illegitimate son of the family housemaid, but the alleged evidence for this is highly suspect. Marx's wife and daughter (Jenny) both predeceased him by some months, and his two surviving daughters (Laura and Eleanor) both took their own lives some decades later. Against the obvious gloom and despair of family life in the political wilderness, there are memoirs and recollections extant of a happy and cultivated family life, of Marx's evident and loving affection for his wife and daughters, and his intense grief at the death of his two sons, Edgar and Guido.

Marx and Engels

Any interpretation of Marx is complicated by the fact that from 1844 until the end of his life he worked closely with Friedrich Engels. Though they wrote only three major works together, they engaged in an extensive and well-preserved correspondence (more than 7000 letters between them are currently extant). They also worked in tandem with political groups, particularly those promoting international cooperation among socialists, such as the International Working Men's Association (1864–76). Engels was a very considerable author and publicist before he met Marx, and was at that time the more famous of the two. He was also an autodidact, having availed himself of lectures and student discussions at Berlin University while he was in the army on Prussian national service. Engels was already a participant in the coded politics of post-Hegelian philosophy, and in the German appropriation of 'English' political economy, publishing an outline 'Critique' in 1844 that influenced Marx significantly. Engels also published an analytical and descriptive account of industrial poverty in *The Condition of the Working Class in England* (1845), based on

published sources and the testimony of his own eyes in Manchester.

As indicated above Engels was a notable publicist and popularizer in connection with Marx's work, and the biographical, intellectual, and political context developed in his accounts from 1859 onward set a profound though not unquestioned model for interpreting Marx. By the later 1860s it is evident from Engels's own works that he himself was increasingly influenced by the development of chemistry and physics as rigorous and mathematically precise sciences, closely linked with industrial processes and with the formulation of a philosophy of science. This eventually flowered as positivism, the view that truth of any kind can only follow from the presuppositions and protocols of a singular scientific method, and that the archetypes for this were physics and chemistry as they progressed to increasingly elegant and powerful theorizations and applications.

Engels's grand project in the 1870s was pursued in his own published works until his death in 1895. This was a synthesis of Hegelian 'dialectics,' which he admired for its ability to cope with change and contradiction, with the natural scientific materialism, on a positivist model, that was proving so successful in the laboratory and the factory. Engels formulated three laws of 'dialectics': unity of opposites, negation of the negation, transformation of quantity into quality (Engels, 1987: pp. 111–132). His view was that the discoveries of the natural sciences could be decoupled from the logical atomism and reductionism that empiricism usually implied, and linked instead to unifying 'dialectical' laws of nature, history, and logic itself. This then would unify and transcend materialism and idealism, science and philosophy, practical truth and logical judgment.

The extent to which Marx came to endorse this system, or even to lean in this direction at all, is keenly debated, and the evidence – textual and biographical – is deeply ambiguous. One of the chief difficulties here is achieving an understanding of Marx and his work that is not already deeply influenced by the canons of interpretation set by Engels, as only in that way could these questions be resolved. Moreover Engels was not only Marx's first biographer, but also the biographer of their relationship, as well as legatee and editor of Marx's articles, and authoritative voice on 'Marx.' Engels was the founder of what was becoming, largely through his own efforts at popularizing and developing Marx's ideas, a body of 'dialectical' thought and socialist practice known as 'Marxism.' Chief among the terms he used to promote these views was 'scientific socialism,' coined during the late 1870s and widely publicized.

Engels and Marxism

Science from Engels's perspective has been far more influential within socialist practice, and also within the developing social sciences, than any conception of science based on a fresh reading of Marx's works. This is unsurprising, given the biographical and political circumstances, and the philosophies of science and social science current from the 1890s through the 1920s. Engels coined the term 'materialist interpretation of history' (later denominated 'historical materialism') and also the notion of 'materialist dialectics' (later reformulated by one of his intellectual successors, Georgii Plekhanov (1856–1918), as 'dialectical materialism').

In this way Marxism was generally expounded as an outlook that integrated philosophical truth and political practice. This was done by presenting history, that is, human society in a developmental sequence, as an instance of scientific knowledge. This scientific knowledge, in turn, was said to be consistent with unifying 'dialectical' laws of nature and logic. Those laws were themselves reflections of the only cosmic reality, that of matter-in-motion, as studied by natural scientists. In that way for Engels, as for Marxists, social science was but a branch of the natural sciences and of philosophical logic, provided that these systems of knowledge were properly understood as unified by a 'great basic process' that was itself dialectical, and so properly captured in Engels's three laws.

In practice Marxist social science was typically organized by the notion that 'history is the history of class struggles,' laid out by Marx and Engels in their *Communist Manifesto* of 1848, and illustrated in the abbreviated account of history as successive 'modes of production' offered by Marx in his Preface to *A Contribution to the Critique of Political Economy* (1859), briefly footnoted in *Capital*, Vol. 1. Marxists defined contemporary political struggle as necessarily and profoundly a struggle between the owners of capital (the bourgeoisie or commercial classes) and the proletarians or workers (those who have nothing to sell but their labor), so their methodology was not merely historical but immediately strategic.

Tactically there were of course numerous difficulties in identifying classes and class-fractions and in finding or rejecting coalition partners for working-class interests. Indeed it was also difficult to define the short- and longer-term interests of the any group of workers at all, particularly with respect to religion, nationalism, and numerous other political expressions of identity and purpose. However, in terms of social science there is no doubt that Marxists were among the leaders in studying and publicizing industrial poverty, class divisions in society, and social protest and revolution. While pre-Marxist political economy was not entirely devoid of a concern for industrial workers as human beings and as political agents, it was not at all comfortable with the idea of any 'more or less veiled civil war' (Marx and Engels, 1976: p. 495). Marxist social science inverted the rather functionalist assumptions of traditional political economy and declared that such warfare was an inevitable stage on the way to human emancipation.

Under communism greater wealth would be produced and distributed in ways far more humane than any money-system of commercial exchange could ever allow. While communism was not itself theorized in any detail, either by Marx or Engels or by subsequent Marxists, the class struggle was itself documented and pursued with single-minded thoroughness. Despite the claims of a dialectical unity of all the social, natural, and logical sciences, this work was persuasive and respected to the extent that it was empirical and evidential. Any claim that Marxism genuinely established a social science different in principles and character from 'bourgeois' science founders on a point of incommensurability (i.e., conventional social scientists did not regard it as science at all because of the 'dialectical' claims, whatever the results) or on a point of disjunction (i.e., the 'dialectical' claims about social science were not the basis of the science that Marxists actually did,

whatever their protestations). In practice self-avowed Marxists focused on class division in industrial societies and characteristically did a social science that claimed to be both scientific and political; conversely any social science preoccupied with working-class poverty was often suspected of Marxist political intent that would bias any scientific results. Clearly, different conceptions of science, and of its relationship with politics, have been operative within the social sciences; Marxist social science highlights and largely constitutes this area of debate.

Orthodoxies and Revisionisms

Marxism became an orthodoxy once it had been challenged, most notably by 'revisionists' in the later 1890s. While this was initially a political challenge concerning the nature and timing of socialist revolution, further doubts were raised concerning the dialectical philosophy of the sciences espoused by Engels and the specific propositions of Marx's critique of political economy. By the 1920s György Lukács could write that orthodoxy in Marxism refers exclusively to method. This position reflected the success of the marginalist revolution in economics, which isolated Marx's critique of political economy as irrelevant, given that traditional political economy had been effectively superseded. It also reflected the success of more sympathetic attempts to adapt Marx's economic work on capitalism to a form of economics that would at least be intelligible to the mainstream. And most of all it reflected a process of rethinking Marx that was just beginning.

This process was aided by the first attempts to produce Marx's published and unpublished works in accessible form (the Marx–Engels *Gesamtausgabe* of the 1920s and 1930s, edited initially by D.B. Ryanzanov). Engels was of course in the edition as well, and the production of his works alongside Marx's inevitably led to comparisons and questions concerning the consistency of their views, particularly with regard to Engels's claims concerning dialectics and science. These questions of interpretation could be answered either way, but most readers were encouraged to see a coincidence of views between the two and to keep the assumptions of orthodoxy intact. This was unsurprising given the political impetus to unity, and to validating a Marxist tradition, that successive scholarly and popular editions of 'Marx and Engels' reinforced. Engels himself, in his foundational 1859 review of Marx's *A Contribution to the Critique of Political Economy* stressed the uniqueness and power of Marx's method even at that early date, suggesting that Marx used both a historical and a logical method and that the two were consistent and coincident.

As the working-class uprisings of the 1920s were suppressed, and as the vacuity of Stalinist thought became evident, 'western' Marxism became more theoretical, more concerned with philosophical and methodological issues, more focused on intellectuals than political leaders, and more academically situated in universities and research institutes, most famously the Institute for Social Research at Frankfurt (in the 1930s and then in a post-Nazi diaspora). The grander claims of Engelsian synthesis were dropped in favor of multidisciplinary inquiry (taking in psychoanalysis, aesthetics, popular culture, imperialism, ethics, and morality, for example). Explanatory reductionism to class (meaning a person's relationship to the means of production) was replaced by a multifactor approach to causation, and an interpretative turn toward diagnosis and persuasion. This latter took place within a 're-Hegelianizing' of Marx, levering him out of an Engelsian frame of scientific causation, explanation, and prediction, and emphasizing his work in conceptualizing long-term phenomena and overarching structures in social development.

This signals an adaptive process whereby Marx has been successively reinterpreted for the social sciences as the intellectual climate, particularly in philosophy of science, has changed. Engels cast Marx in the shadow of Darwin's 'discoveries' and of a positivist account of natural science (doing considerable violence to Hegel and Darwin in the process). Later Marxists reinterpreted Marx in the light of neo-Kantian epistemologies and ethical doctrines, and in the light of the burgeoning empirical social sciences. After World War II Marxists such as Louis Althusser (1918–90) adapted Marx to structuralism, producing an account of history and social development that reduced human agency to a mere effect of economically driven and only partly predictable large-scale social forces. Althusser proposed to distinguish a nonscientific from a scientific Marx, and Marx was said to have attained this intellectually by making an epistemological 'break' and so expunging from his thought any trace of Hegelian idealism. Althusser's project was never satisfactorily completed and is noteworthy for its method, that of an intense and large-scale rereading of Marx, always attempting to fit his ideas into a binarized frame, for example, nonscience versus science, humanist versus materialist.

Perhaps unsurprisingly the contrary reading, that the apparently Hegelian, 'humanist' Marx of the early works is the valuable one, gathered strength at about the same time. Marx's 'Economic and Philosophical Manuscripts' of 1844 were published substantially for the first time in French and English in the late 1950s, and attracted considerable attention from scholars and readers who were intellectually or temperamentally repelled by the aridities of orthodox dialectics. Any social science presupposes various facts or truths about human beings (or 'man,' as he appeared in those days before feminist critique). The 'humanist' Marx was also a reflection of dissatisfaction with behaviorist models that pictured humans as reactive systems, responding to stimuli in predictable ways. The 1844 articles could be read in isolation from any other works by Marx, and frequently were. They appeared to be self-contained meditations on human nature and history, delineating a story of necessary and progressive interactions with nature leading ultimately to the high productivity of modern industry and the discoveries in the natural sciences that made this possible.

Marx's early articles present 'man' as an inherently social being, necessarily engaged in a sensuous 'metabolism' with nature, which is effectively an external but essential part of the body. Labor, in Marx's view, is not merely a vital activity for satisfying needs (as with animals), but rather in the case of humans a 'free conscious' activity that takes human life itself to be an object and fashions things 'according to the laws of beauty,' Humans produce even when free from physical need, and only truly produce when production is freely undertaken.

This claim is meant to have descriptive force, distinguishing self-conscious, and self-reflexive activity undertaken by humans from the life activities undertaken by animals, said by Marx to be merely self-identical with what they do. Humans, in his view, produce themselves in different ways, as different kinds of people (intellectually and physically) in different productive cultures. Communism, in this scheme, is a way of making this self-constructing process more explicit in terms of egalitarian decision making in society.

The inverse of communism that Marx portrays in his articles is the contemporary world of 'alienated' labor, in which the worker is estranged in terms of possession and power from the products of labor, other workers, nature, society at large, and from the quintessential human species-activity, namely creative work. This philosophical analysis sets a context for the consideration of private property as the contemporary system through which production and exchange take place, and Marx offers his account of 'man' as an alternative to the schemes developed in classic texts of political economy, most notably the highly individualized yet commercially minded hunters and fishermen portrayed in the work of Adam Smith (1723–90).

'Alienation' (Term used by Marx in early writings but not wholly abandoned later, when more specific terminology was employed. It characterizes work-relations within which workers and products, workers and productive activities, social relations among workers, and work as the defining human 'species-activity,' are all experienced in ways that are at odds with or separated from 'truly human' modes of fulfillment. Alienation was the hallmark of the 'humanist' revival of Marx in the early 1960s, and has been controversially deployed to distinguish a 'young' or 'early' Marx from a 'mature' Marx of the later works.) is used as a general term by Marx for detailing the specifics of class division in commercial societies, and in the early articles he endeavored to spell these out with respect to workers, and also to nonworkers (though he spent little time on this). The thrust of Marx's argument was toward the overthrow of capitalist society as in no one's interest as a human being. This was precisely because material and psychological deprivation contradicted the inherent potential of the human species-being. Notwithstanding the political and metaphysical tinge to Marx's exposition, alienation functioned in the 1960s and 1970s as an empirical catchall concept for sociological and psychological research into and evaluation of modern industrial processes.

Perhaps the most significant development in Marxist social science in the later twentieth century has been the discovery and appropriation of the work of Antonio Gramsci (1891–1937), an Italian communist trade union activist imprisoned by the Fascist government from 1926 to 1935. During his years in prison he composed a lengthy set of political notebooks, which gradually became available after World War II. His views have a distinct affinity with those of the early Lukács and other 'Hegelian' Marxists, at least to the extent that he departed decisively from the supposed certainties and mechanistic models of dialectical materialism. While he did not have access to Marx's early articles, again there is an affinity with the style of thought and political thrust of these works.

Gramsci was in any case facing the problem that a proletarian revolution, declared inevitable by orthodox Marxism, did not seem to be happening in a steady historical development. Far from class position translating easily into political radicalism, his analysis revealed that cultural conservatism was deeply ingrained in peasants and workers, and that inculcating class-conscious political activism would necessitate an ideological counteroffensive to this already existing 'hegemony.' His work inspired a Marxist social science deeply concerned with tracing the flow of power in society into channels that were not reducible, or not directly reducible, to class position and economic circumstances. Ideas, ideologies, and institutions all became much more important in constructing an analysis of contemporary class politics and a set of political strategies and tactics. While this may have seemed to deemphasize Marx's lifelong project – a critique of the economic categories – it actually mirrored the methodology and content of his writings on contemporary politics, notably *The Class Struggles in France* (1850) and *The Eighteenth Brumaire of Louis Bonaparte* (1852). This Gramscian reading of Marx, then, is another way that he has been reread and reinterpreted, taking a fresh look at which of his texts is most relevant to the times.

For the social sciences Marx and Marxism offer a rich and varied tradition of inquiry and debate, posing difficult questions about objectivity and neutrality in a social science, about what sort of knowledge counts as scientific, and about what sort of intellectual and practical activity science as a whole actually is. These questions may be answered in terms of contextualized readings of Marx, Engels, Marxism, and later interpreters. How directly those contextualizations map onto current circumstances is very much a matter of judgment by those interested in the social and behavioral sciences today, but there is no doubt that many would set a positive value on what a rereading of this tradition can contribute in the present. Indeed it is likely that most educators would count at least a knowledge of this tradition to be essential for any social scientist, whatever their interests. This itself is a tribute to the wide-ranging and as we would say today 'interdisciplinary' value of the legacy left by Marx.

Marx's major works, including the *Economic and Philosophical Manuscripts*, *The German Ideology*, the *Communist Manifesto*, *The Eighteenth Brumaire of Louis Bonaparte*, the *Grundrisse*, the three volumes of *Capital*, and the three volumes of *Theories of Surplus Value*, have all been published in numerous editions and translations and are widely available in English.

The definitive edition of the complete works of Marx and Engels published in their original languages is the renewed *Marx–Engels Gesamtausgabe* (known as MEGA). This was begun in 1975 under communist party sponsorship and published by Dietz Verlag in East Berlin. It is now being continued by an international consortium (IMES) based at the Berlin–Brandenburg Academy of Social Sciences and is being published by Akademie Verlag. The series includes all published and unpublished works, articles, letters to and from Marx and Engels, third party letters, and considerable bibliographical and contextual background in the notes and apparatus. Current plans are to complete the series in approximately 114 volumes within the next decade.

A vast and scholarly selection from the Marx–Engels materials is published in English in a set of 50 volumes, begun in 1975 and completed in 2004. This is the *Collected Works* from Lawrence & Wishart (London).

Abstract

This article treats marxism as an ongoing and evolving research program based on a number of questions, categories of analysis, and theses specified by Karl Marx. Marxism constitutes a vibrant research program that spans all of the social science disciplines and many of the humanities. This article briefly discusses the assimilation of marxism into sociology and the use of marxism within sociology, before turning to the project of building the marxist research program, with a particular emphasis on contributions by sociologists. The research program can be summarized in terms of seven theses, which fall under three theoretical clusters: (1) the social construction of reality, (2) historical materialism, and (3) the contradictory and problematic reproduction of capitalism.

Karl Marx's work combined a distinctive political philosophy, building on the body of Western philosophy from Plato to Hegel, with a theory of political economy building on and singularly advancing the entire corpus of political economy to his day. The result was a grand theory of human history that provided foundational building blocks for the emerging discipline of sociology.

In the twenty-first century, marxism continues to guide vibrant research traditions in sociology, political economy (e.g., Baran and Sweezy, 1966; Bowles and Gintis, 1976; Gordon, 1976; Foley, 2000; Lebowitz, 2003; Duménil and Lévy, 2004; Brenner, 2005; Kliman, 2007; Foster and Magdoff, 2009; Moseley, 2009; Lapavitsas, 2011; Amin, 2013; Aglietta, [1979] 2000), political science (e.g., Wood, 2003; Panitch and Gindin, 2004; Callinicos, 2009a), political theory (e.g., Ollman, 1977; Callinicos, 2009b), philosophy (e.g., Lukács, 1971; Bhaskar, 1979; Mészáros, 1995; Hardt and Negri, 2000; Lazzarato, 2006; Smith, 2013), management (e.g., Adler, 2007; Böhm and Land, 2009), economic geography (e.g., Harvey, 1982), ecology (e.g., Foster, 1999; Clark and York, 2005), history (e.g., Anderson, 1974; Wallerstein, 1974; Brenner, 1976; Hobsbawm, 1994), literary criticism (e.g., Eagleton, 1976; Jameson, 1991), and media studies (e.g., Caraway, 2011). As evidence of such vibrancy, one need only consider the remarkable range of academic journals that were founded by marxists and continue to provide outlets for marxist social science and humanities:

- *Science and Society: A Journal of Marxist Thought and Analysis* (1936–present)
- *Monthly Review: An Independent Socialist Magazine* (1949–present)
- *New Left Review* (1960–present)
- *Socialist Register* (1964–present)
- *Telos* (1968–present)
- *Antipode: A Radical Journal of Geography* (1969–present)
- *Critical Sociology* (1969–present)
- *Capital & Class* (1977–present)
- *International Socialism: A Quarterly Journal of Socialist Theory* (1978–present)
- *Socialism and Democracy* (1985–present)
- *Rethinking Marxism: A Journal of Economics, Culture & Society* (1988–present)
- *Capitalism, Nature, Socialism* (1988–present)
- *Journal of World-Systems Research* (1995–present)
- *Cultural Logic: An Electronic Journal of Marxist Theory and Practice* (1997–present)
- *Historical Materialism* (1997–present)
- *International Socialist Review* (1997–present)
- *The International Marxist-Humanist* (2000–present)
- *Mediations: Journal of the Marxist Literary Group* (2007–present)
- *New Proposals: Journal of Marxism and Interdisciplinary Inquiry* (2007–present)

As the foregoing might suggest, it is difficult to specify what would distinguish 'marxist sociology' from other forms of academic marxism. Marx's research program, known as historical materialism, was explicitly conceived as a unified theory covering all of the modern social science disciplines and many within the humanities. Many subsequent marxists have – even when trained within particular disciplines – continued to work within the fundamentally transdisciplinary historical materialist research program. At the same time, many core marxist questions and categories have become assimilated into sociology, and marxist sociologists have often explicitly used marxism to engage disciplinary questions addressed by competing or complementary theoretical frameworks. This article briefly discusses the assimilation of marxism into sociology and the use of marxism within sociology, before turning to the project of building the marxist research program, with a particular emphasis on contributions by sociologists.

Assimilating Marxism into Sociology

Most sociologists, even those relatively unsympathetic to the theoretical and political agenda of marxism, recognize that the marxist tradition has been the source of a central theoretical current within sociology. Marx, Weber, and Durkheim are widely considered to be the founding fathers of sociology. Durkheim is identified with norms and problems of social integration, Weber with rationalization and the cultural sociology of meaningful action, and Marx with class, power, and conflict. Studies of politics routinely borrow from the marxist tradition a concern with the influence of business on the state, broader economic constraints on state action, and the class bases of political parties and political mobilization. The sociology of

work has been largely defined by marxist concerns with the problem of extracting effort from workers, managerial control systems, worker resistance, and the impact of technology on skills. The marxist concept of contradictions is used in discussions of social change. Theories of social conflict are influenced by the core marxist idea that conflicts are generated by structurally based social cleavages, not simply subjective identities. Marx's discussions of the relation between material social relations, ideology, and consciousness played a fundamental role in the development of the theory that reality is socially constructed (Berger and Luckmann, 1966). In these and many other ways, themes integral to the marxist tradition have been imported into the mainstream of sociological scholarship, frequently losing any explicit link to their marxist pedigree in the process.

Using Marxism within Sociology

Many marxists have engaged in a more self-conscious, more ambitious use of marxist ideas within sociology. Here the idea is to take the conceptual framework elaborated within the marxist tradition – mode of production, exploitation, the labor process, class structure, class struggle, class consciousness, the state, ideology, revolution, and so on – and to use these concepts to understand a wide array of sociological problems. The goal is for marxist concepts to challenge the mainstream with an alternative set of explanations and predictions, rather than lose their identity by being absorbed into the mainstream. In studies of political elites, the claim is not just that every society has a 'governing elite,' entry to which is based ultimately on merit, but that ownership of the means of production provides the material basis for a relatively cohesive and powerful 'ruling class' (e.g., Bottomore, 1964). Similarly, in studies of the state, the claim is not just that there may be business influence and economic constraints on state policies, but that class power sets fundamental limits on the range of possibilities of state action (e.g., Miliband, 1969; Offe, 1984). In studies of corporations, the claim is that the diffusion of ownership among shareholders has not led to a separation of ownership from control, hence destroying the old class structure of workers and owners, but that groups of proprietary owners are still able to realize their corporate objectives by maintaining controlling shares across corporations and investment banks (e.g., Zeitlin, 1974). In studies of work organization and technology, the claim is not just that employers face a problem of gaining cooperation from workers and getting them to perform with adequate effort, but that the antagonism of interests between workers and employers is a fundamental property of work organization in capitalist economies (e.g., Braverman, 1974). In studies of inequality, the claim is not just that class is one of the salient dimensions of social inequality in industrial societies, but that class relations structure fundamental features of the system of inequality (e.g., Wright, 1985).

Building the Marxist Research Program

To understand the tasks involved in building the marxist research program, it is necessary to briefly lay out the core substantive arguments of the marxist tradition. Such an exercise will always be contested because Marx's voluminous *oeuvre* was evolving and unfinished. Marx's thought evolved over the three decades in which he wrote and many of his writings consist in unfinished and unpublished manuscripts, often in fragments. Additionally, while Marx typically mixed academic analysis and political writing in the same texts, some of these – perhaps most notably *The Communist Manifesto* – were heavily political documents that clearly presented extreme simplifications of his extensively elaborated and deeply nuanced theoretical analysis (the Penguin versions of *Capital, vols. 1–3* total 2851 pages and *The Grundrisse* 904 pages).

This article thus treats marxism as an ongoing and evolving research program based on a number of questions, categories of analysis, and theses specified by Marx. The research program can be summarized in terms of seven theses, which fall under three theoretical clusters: (1) the social construction of reality, (2) historical materialism, and (3) the contradictory and problematic reproduction of capitalism.

The Social Construction of Reality

Marx developed a basic sociological theory of social structure and human agency, perhaps the earliest version of a theory of the social construction of reality. The core of this theory can be stated in terms of one ontological presupposition and two theses.

Ontological presupposition: The social world consists of surface appearances and underlying reality, in which the former typically mystify the latter.

Plato introduced the argument – most famously in his allegory of the cave – that reality is not what we observe directly but exists in nonmaterial, abstract forms. Marx accepted the distinction between appearance and reality, but inverted Plato's idealism, positing that underlying reality consists of material social relations (Wolff, 1988). Appearances, in Marx's version, are manifestations of material reality, but distorted ones. In Marx's ([1894]1981) own terms, "All science would be superfluous if the outward appearance and the essence of things directly coincided." The classical economists focused only on exchange, misrepresenting the market as a new realm of equal exchange and missing the fundamental importance of 'the hidden abode of production.' Their theories posit a world of individuals and things (commodities), thus failing to appreciate how social relations constitute individuals and produce commodities. "The individual and isolated hunter fisherman, with whom Smith and Ricardo begin," Marx ([1857–1858]2000: p. 83) observed, "belongs among the unimaginative conceits of the eighteenth-century Robinsonades." In order to flesh out this presupposition, to develop it into a scientific theory, Marx articulated a thesis on the social construction of reality, which is most easily understood in terms of two subtheses.

Thesis 1a: Humans produce the social world, including individual consciousness of it, through labor.

Thesis 1b: Human agency drives historical change, but individual consciousness is shaped by institutional context.

In a preface to an otherwise less-influential work, Marx ([1859]1977) wrote that social consciousness in any society 'corresponds' to the political and ideological 'superstructure,'

which 'arises' on top of the relations of production. This has often been read to suggest that the economic structure of society determines the political and cultural superstructure, but a wider reading of Marx shows that for him, even the 'material forces of production' were seen as a social and historical product (Nicolaus, 1968). Elsewhere Marx wrote forcefully that in the act of labor, understood in its broadest sense, humans produce not simply material wealth but themselves as human subjects, and therefore society as a whole (Marx and Engels, [1846]1996). Read through this lens, the distinction between base and superstructure is an analytical distinction of the process by which the social world – politics, culture, ideology – is produced *with and through* the core of human activity, labor.

Thesis 1a is best understood, then, as the proposition that cultural understandings and political institutions are *coproduced* with human economic activity. While consciousness and culture (and politics) correspond to the economic structure of society, then, this should not be reduced to an argument that particular material relations mechanically generate particular forms of thought, let alone specific contents of thought. The corollary argument (Thesis 1b) is that as the ideological forms – ways of understanding the world, conceptual frameworks, and cognitive institutions – are transmitted across generations, they come to preexist particular individuals, who are socialized in the context of existing ideologies (see Thesis 5 below for an elaboration in terms of class structure and consciousness). As Marx wrote in a justly famous passage:

> Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances directly encountered, given and transmitted from the past. The tradition of all the dead generations weighs like a nightmare on the brain of the living.
>
> Marx, [1852]1994

Marx's theory of social constructionism includes the additional thesis that social relations are often constructed in inherently contradictory ways.

Thesis 2: The material social relations that humans produce are often constituted, in part, by dynamic contradictions.

As he did with Plato's idealist distinction between appearance and essence, Marx also inverted Hegel's idealist notion that thought develops through the progressive working out of the inherently contradictory nature of categories. For Marx, structural contradictions – internal antagonisms – exist within the material relations that humans socially construct. Specifically, a structural contradiction exists where two social entities are constituted as part of a mutually interdependent relationship and these two entities are potentially in conflict (Callinicos, 2009b). Where structural contradictions exists social relations are said to be dialectical, that is, each social entity in the social relation has causal impacts on the other. The two primary contradictions of any society (Thesis 3 below) are between (1) the forces and relations of production and (2) classes. These primary contradictions provide a fundamental source of dynamism in human society (Thesis 4) and give rise to a number of secondary contradictions (Thesis 7).

Historical Materialism

Marx's theory of history consists of three core theses. The first thesis is most easily understood in terms of three intimately connected subtheses.

Thesis 3a: All existing societies have been fundamentally structured by a mode of production, constituted by the dialectical interaction between forces of production and relations of production.

Thesis 3b: Primary contradiction I: The relations of production have historically constituted an antagonistic class structure objectively based on the relations of producers and nonproducers.

Thesis 3c: Primary contradiction II: The forces of production will tend to develop and will increasingly conflict with the relations of production.

Human history develops in terms of modes of production. The forces of production include the means of production (technology and raw materials) and labor power. The relations of production refer to (1) the relations of ownership over the means of production and (2) the mode of appropriation of surplus labor of direct producers (slaves, serfs, wage laborers) from nonproducing owners (slave owners, feudal lords, capitalists). The class structure is objectively determined by the two aspects of the relations of production, which vary across modes of production: (1) ownership of the means of production, which is a fundamental source of power in society, and (2) relations between direct producers and nonproducers in society.

Under feudalism, serfs owned some means of production (subsistence farming tools and perhaps a small amount of land) but not enough land to be self-sufficient. Land-owning feudal lords were the nonproducing class, which appropriated surplus labor from serfs in the form of rent, based on extra-economic feudal obligations. Under capitalism, there are a number of ways in which classes become internally differentiated and contradictory class locations emerge (Wright, 1985). The basic class structure remains one in which workers have been dispossessed of any means of production and capitalists, as nonproducing owners, extract surplus labor of wage laborers, nonowning direct producers, through the economic mechanism of the wage. The latter is a mystified relation which appears to compensate for an entire period of labor but actually compensates only for the labor necessary to reproduce the workers (Thesis 6; Burawoy, 1979; Marx, [1867] 1990).

Thesis 3c submits that the forces of production have a tendency to develop, due to attempts of direct producers to adopt labor-saving innovations (Callinicos, 2009b), which, eventually, will come into conflict with existing relations of production, leading to an intensification of this fundamental contradiction (see Thesis 7). Ultimately, pressure will be put on the existing class structure as its fettering of the productive forces becomes increasingly problematic, and as emergent classes are brought forth due to the changing economic structure of society.

Thesis 4: The intensification of the primary contradictions will force attempts to mitigate or displace them, the outcome of which will depend on the state of the class struggle.

So-called orthodox marxism is defined by the expectation that the intensification of the primary contradictions will

inevitably lead to the overthrow of the bourgeoisie by the proletariat and the establishment of a socialist society (for the most sophisticated articulation of this, see Cohen, 1978). This position is based on a narrow reading of Marx found in a political pamphlet (Marx and Engels, [1848]1948) and crisp but brief preface to a later work (Marx, [1859]1977). A less deterministic reading is as follows. The contradiction between the forces and relations of production has an inherent tendency to intensify. There may be various forms of temporary class compromise, but the class struggle will tend to develop a number of associated secondary contradictions rooted in the primary contradictions that will produce crises (Thesis 7a) and thus require attempts to mitigate or displace the crisis tendencies (Thesis 7b). Such displacement or mitigation may take many forms through various spatial and institutional fixes (Harvey, 1982; Aglietta, [1979]2000), but these will always be temporary as the primary structural contradictions can never been completely eliminated. Actual outcomes will ultimately depend on the class struggle (Brenner 1976; Chibber 2011), fought on the terrains of politics and ideology as well as economic relations. The role of ideology is central to marxist class analysis.

Thesis 5: The relationship between objective class relations and individual consciousness is mediated by ideology.

Marx wrote about ideology in at least two different ways. The first is the notion of false consciousness. Here the distinction is between a real, scientific grasp of reality, versus a distorted or incorrect, ideological understanding. However, the more influential reading has focused on Marx's second conception of ideology as the entire medium of consciousness and meaningfulness. This second reading has been developed in two primary, and not inconsistent, ways. The Italian theorist Antonio Gramsci developed ideology in terms of the concept of hegemony, referring to the political and moral leadership by which the capitalist class incorporates the working class into society. Hegemony is an attempt to present the interests of the ruling class as the universal interests of society but, crucially, to be effective it must have a material basis in the 'concrete coordination of interests' between the ruling class and subordinate groups (Gramsci, 1999[1929–1935]: pp. 182, 161). The French philosopher Louis Althusser ([1970]2001) argued that ideology constitutes individuals as conscious actors and patterns their behavior through discourse, conceptual frames, categories, and images.

All ideologies have some basis in material social relations, although ideology itself has discursive as well as nondiscursive determinants (Therborn, 1980). Language is the medium through which material things are represented, but language is multireferential: different meanings can be constructed around the same material relations, such as the market and the labor process, although some representations will be more distorted (in the sense of being 'one-sided') than others (Hall, 1986). Thus, although class position does not determine one's consciousness, ideologies – including hegemonic class ideologies – provide representations of material structures, including class structure. Class ideologies interact in complex ways with nonclass ideologies, most importantly gender, religion, nationality, and race. Material relations of patriarchy, for instance, give rise to gender ideologies. Capital accumulation becomes accommodated to patriarchal relations in a way that tends to perpetuate the latter, although in modified form – for instance, in terms of the early- to mid-twentieth century family model of male breadwinning in the labor market and female child rearing and homemaking (Hartmann, 1979). Understanding these complex social processes requires careful attention to ideology and its material bases. Indeed, it has been argued that non-marxist theories of the intersectionality between class, gender, and race have amounted to an endless series of descriptive empirical studies of their combined effects in specific contexts, without explaining the underlying sources of such inequalities (Gimenez, 2001). Gender, race, and nationality surely have their own material bases, but they interact with class in a macroinstitutional system where class power remains fundamental insofar as it is economic power, however much gender/race/nation modify this and are irreducible to it (on nationality and ethnicity, see Anderson, 2010).

The Contradictory and Problematic Reproduction of Capitalism

The contradictory nature of capitalism and its problematic reproduction can be stated in terms of two theses, the second of which consists of two subtheses.

Thesis 6: The output of capitalist production consists of commodities, whose underlying values – which can take the form of both use-values and exchange-values – are objectively determined by the minimum socially necessary labor time required to produce them, with the primary source of profit being the surplus labor of workers.

This proposition develops the ontological assumption about the distinction between appearance and reality into a complex and often-misunderstood thesis on the value forms of capitalism. Capitalist societies produce wealth in the form of commodities, which have use-value (when consumed) and exchange-value (when traded for other use-values). Exchange-value is necessarily the form in which value is expressed (and appears). Capitalist production is not driven by consumption (use-values), as Adam Smith and his followers would have it, but by capitalists' desire for accumulation (exchange-values). Capitalists pay workers only the equivalent of their necessary labor time, that is, the amount of time necessary for a worker to produce his or her own livelihood according to the basic standard of living of the era. Any and all additional working time – surplus labor time – is the source of profit. The underlying value of a commodity is determined by the labor time socially necessary to produce it: "the labor-time required to produce any use-value under the conditions of production normal for a given society and with the average degree of skill and intensity of labor prevalent in that society" (Marx [1867] 1990: p. 129).

Although marxist value theory is seen by many critics primarily as a theory of price determination, it is more fundamentally a social structural theory of how labor is valued under capitalism. Marx used the example of the power loom, which, he estimated, cut by half the labor time necessary to weave a certain quantity of yarn into cloth. Capitalist competition thus forced wages down to the new level of socially necessary labor-time, and as a result cut prices accordingly. However, the critics have succeeded in narrowing marxist value

theory to a technical question of the relation of money prices to labor values, which is mathematically complex and contested, and has led some marxists to reject the thesis, and many left academics to reject marxism altogether. Yet, in Marx's own work the question of prices was secondary to the larger theory of value relations and the fetishism of commodities. Commodities *appear* to have an intrinsic value in terms of their money price, independent of any social relations. But the world of money prices is a very bizarre world – the value of commodities was represented by classical political economy in terms of the amount of labor congealed within them – which mystifies the underlying social relations that value labor and produce profit (Wolff, 1988).

In terms of prices, socially necessary labor-time sets limits on the movement of prices; since they may fluctuate around underling values for a number of reasons, the relationship between labor-values and product-prices is probabilistic. Marxist economists continue to defend and elaborate the labor theory of value in terms of the relation between values and prices (e.g., Foley, 2000; Kliman, 2007), although these developments are beyond the scope of this article. In terms of the broader labor theory of value, the distinction between use-value and exchange-value – rooted in the contradiction between the forces and relations of production – is the basis for a number of secondary contradictions, to which we now turn.

Thesis 7a: Capitalism is a fundamentally dynamic political economic system that is progressive insofar as it greatly enhances human productive capacity, but has inherent tendencies toward disequilibrium and crisis.

Thesis 7b: Capitalism thus requires spatial and institutional fixes to secure temporary periods of stability and ensure its (expanded) reproduction.

It is often forgotten by critics that Marx was among the first scholars to note and praise the fundamental dynamism and progressivity of capitalism, in particular the extent to which it enhances the productive capacity of human society. While the orthodox marxist position predicts the inevitable decline of capitalism, a more nuanced, less teleological formulation is that (Thesis 7a) due to its inherent contradictions, capitalism is systemically characterized by disequilibrium and regular episodes of crisis and institutional decay. The corollary (Thesis 7b) is that the contradictory social relations of capitalism require various spatial and institutional fixes for their reproduction (Harvey, 1982; Aglietta, [1979]2000). Marx identified four crisis tendencies within capitalism.

The central crisis tendency is toward overaccumulation, which arises from the contradictions between the forces and relations of production (and between use-value and exchange-value). Competing capitalists tend to develop the forces of production without regard for the limits of the market (Clarke, 1988). Fueled by credit, capitalists will attempt to overcome the limit of the market by expanding production, and some will be successful in expanding it by making cheaper products or creating new ones, but the economy will always hit a new limit as innovations are generalized. This results in periodic crises of over-accumulation – a surplus of capital with a lack of sufficient outlets for investment – in which capital is devalued, capacity destroyed, and unemployment increased through bankruptcies, mergers, and acquisitions (Harvey, 1982; Foster and Magdoff, 2009). Such crises set the stage for renewed profitability and accumulation. This primary contradiction also generates secondary contradictions in the labor process. The labor process, cooperation to create a product, is part of the productive forces. The valorization process, the extraction of surplus labor to produce a profit, is part of the relations of production. While valorization pressures in the form of competition among capitalists stimulate the development of the productive forces, they also have detrimental effects on the labor process, because capitalists may have to sacrifice some efficiency in order to ensure control of labor (Gordon, 1976), and on the workforce, because the pursuit of profit takes place without regard for worker well-being (Adler, 2007).

Capitalism generates three additional crisis tendencies: a declining profit rate, underconsumptionism, and metabolic rift. First, as capitalists seek to compete by substituting machines for labor (the sole source of new value), they put downward pressure on profit rates (Kliman, 2012). This also generates a secondary contradiction in the labor market, as the systematic substitution of capital for labor means that technical change destroys more jobs than it creates, making paid work increasingly unable to provide the basis for improving the livelihood of the whole population (Aronowitz and DiFazio, 1994). Further downward pressure on the profit rate may be generated if labor succeeds in its demands for higher wages, as happened across the OECD in the late 1960s following the postwar class compromise. However, when capital gains the upper hand in open class struggle, as happened following the late 1960s profit squeeze, the second crisis tendency of underconsumptionism will become manifest. These crisis tendencies lead capitalists and capitalist state managers to adopt a number of strategies to offset or displace them. The role of the state is critical because market forces alone cannot secure the reproduction of capitalism, which requires extra-economic forms of regulation (Jessop, 2002). However, this gives rise to a secondary contradiction between the national form of the state the inherently global nature of capitalist accumulation, leading, for instance, to various well-known crises of Keynesianism (Clarke, 1988).

Among the oldest strategies to overcome the limit of the market and displace crises is the spatial fix of expanding markets. Indeed, capitalism has always been a world economy, in which states in the core of the world economy appropriate surplus from peripheral states, with semiperipheral states providing a form of political stability (Wallerstein, 1979). The history of capitalism as a world system has occurred in four systemic cycles of accumulation, in which a hegemonic state leads in terms of a material expansion and then shifts to a financial expansion, signaling its decline and the rise of a new hegemon (Arrighi, 1999). The Genoese cycle ran from the fifteenth to the early seventeenth century, the Dutch cycle from the late sixteenth through to the eighteenth, the British cycle from the latter half of the eighteenth through to the early twentieth century, and the US cycle from the late nineteenth century through its current phase of financialization.

Financialization in the US since the 1970s – the increasing role of financial activities in generating profit – has grown out of the general condition of overaccumulation: a surplus of

capital and a lack of sufficient outlets for productive investment (Foster and Magdoff, 2009). This, in turn, is the fundamental basis of the 2007–08 financial crisis, as rampant speculation in the face of declining investment opportunities in the real economy led to the development of a raft of esoteric financial instruments, a housing bubble, and predatory mortgage lending. These crisis tendencies were contained in the US and Western Europe from 1945 to around 1970 through a fordist institutional infrastructure (Jessop, 2002; Aglietta, [1979] 2000), consisting of the Bretton Woods system – fixed exchange rates and capital controls, which allowed national policy autonomy for Keynesian welfare states – along with states internally structured in terms of producer-driven supply chains and oligopolistic competition in core sectors. This fordist structural context allowed various national high-wage class comprises (Vidal, 2013). The institutional fix of the fordist accumulation regime was based in the ability of national states to limit the downward pressure exerted on wages by global competition. As this fix eroded under financialization, internationalization, and neoliberalism, the contradictions of capitalism have reasserted themselves with a vengeance. There is no clear fix to the twin problems of rising inequality and stagnant growth affecting the OECD economies.

The fourth crisis tendency is ecological. Marx discussed ecological sustainability in terms of a metabolic relation between humans and nature, arguing that large-scale capitalist agriculture created a metabolic rift between humans and the soil, as capitalism was unable to maintain sufficient recycling of soil nutrients (Foster, 1999). The rift is most developed today in terms of the carbon cycle, which has been ruptured by the accumulation of CO_2 in the atmosphere, overwhelming the capacity of natural sinks to absorb the additional carbon produced under capitalist production (Foster et al., 2011). It remains unclear how the ecological rift can be fixed within a growth-driven, capitalist economy.

Marxism–Leninism: The Ideology of Twentieth-Century Communism

William J Morgan, University of Nottingham, Nottingham, UK

© 2015 Elsevier Ltd. All rights reserved.

This article is a replacement of the previous edition article by S.E. Hanson, volume 14, pp. 9298–9302, © 2001, Elsevier Ltd.

Abstract

The article considers Marxism–Leninism as a political ideology, its foundations as developed by Karl Marx (1818–83) and F. Engels (1820–95), its characteristics as established by V.I. Lenin (1870–1924), and its consolidation by J.V. Stalin (1879–1953) between 1922 and 1953 through 'socialism in one country' and the Communist International (Comintern). The article also considers critics of Marxism–Leninism, the transition from Comintern to the Soviet agencies of the Cold War, and support for national liberation movements. The final section considers the condemnation of Stalin by the Communist Party of the Soviet Union, attempts at revisionism, the impact of Gorbachev, the collapse of the Soviet Union, and the end of Marxist–Leninism as a dynamic ideology.

Introduction

Marxism–Leninism was the official ideology of the former Union of Soviet Socialist Republics (USSR) and by extension of the international communist movement during the twentieth century. The purpose of this article is to set out succinctly the origins of Marxism–Leninism as a political ideology, its foundations in the philosophy of history developed by Karl Marx (1818–83) and his collaborator F. Engels (1820–95), its characteristic features in revolutionary political theory and practice as established by V.I. Lenin (1870–1924), and its consolidation and operation by J.V. Stalin (1879–1953), effectively from 1922 until 1953. This was achieved through the application of the fortress doctrine of 'socialism in one country,' and through the paradoxical tool of the Communist International (Comintern), which organized and controlled foreign communist parties according to the political needs of the Soviet Union. The article also considers revolutionary critics of Marxism–Leninism and controversies that affected the application of the ideology in practice. The transition from the Comintern to the Communist Information Bureau (Cominform) and other Soviet agencies of the Cold War, including support for national liberation movements, is also considered. There is a final section on the condemnation of Stalin by the Communist Party of the Soviet Union (CPSU), attempts at revisionism and reform, the impact of Gorbachev, the collapse of the Soviet Union, and the end of Marxism–Leninism as a dynamic ideology.

Marx and Marxism

It is clearly necessary to begin with the philosophy of history developed by Karl Marx. This has given rise to a voluminous literature of analysis and comment, as well as to bitter ideological dispute. Marxism is based on the philosophical theory of dialectical materialism. Its fundamental principles are well known and will only be summarized here. In his early writings, Marx developed the concept of *alienation* with its roots in the labor process under capitalism. According to this system, the mass of the population was compelled by private ownership of production to work as employed labor or to be unemployed and destitute. Marx believed that such economic relations were fundamental to social and political relations. This is explained through his famous, if subsequently contentious, *base and superstructure* metaphor. In a classic passage in the *Preface to a Contribution to the Critique of Political Economy* written in 1859, Marx said: "The mode of production of material life conditions the social, political and intellectual life process in general. It is not the consciousness of men that determines their being, but, on the contrary, their social being that determines their consciousness" (Marx and Engels, 1968: 181). In other words, as the components of the economic base change, so does its influence on political, social, and cultural institutions, such as the family and the state, which comprise the superstructure. The contention is whether the relationship between base and superstructure is simple and deterministic or one that is complex and dialectic. Marx was, fundamentally, a theorist of capitalism rather than socialism (about which, logically and empirically, he could say very little). In *Capital* (1990), his most detailed work, he analyzed the structure of capitalism, elaborating a labor theory of value, a theory of capital accumulation, and a theory of commodity fetishism, with their implications for his earlier concept of human alienation.

Marx did not complete his planned study, but believed that in *Capital* he had shown that the capitalist system of ownership and production contained the seeds of its own destruction, and that economic and social revolution must follow once this process of decay was complete. The key to Marx's analysis is not the poverty of the proletariat in absolute terms, especially given the productive possibilities of technical advance, but its exploitation in the production of surplus value, over the disposal of which it had no control. This is important given revisionist debates. This analysis was, according to Marx, the key to understanding historical change and as he and Friedrich Engels declared in the opening pages of *The Communist Manifesto*: "The history of all existing society is the history of class struggles" (Marx and Engels, 1986: 79). Thus, slave societies had given way to feudal relations that had been replaced by capitalist employment relations. These, Marx predicted, would give way to socialist ownership and employment relations,

which would be brought about through proletarian or worker revolution and the expropriation of the capitalist class.

Each economic and social transition depended on active human intervention. As Marx said in his celebrated eleventh thesis *On Feuerbach*, while hitherto: "The philosophers have only *interpreted* the world in various ways, the point however is to *change* it" (Marx and Engels, 1968: 30). In another famous passage, this time from *The 18th Brumaire of Louis Bonaparte* (1852), Marx had recognized: "Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances, directly found, given and transmitted from the past" (Marx and Engels, 1968: 96). Marx and Engels had developed a revolutionary praxis aimed at liberating humanity from its passive and alienated existence. As Engels said at the graveside of his friend and comrade: "For Marx was before all else a revolutionist…. Fighting was his element" (Marx and Engels, 1968: 430).

However, the exploratory and essentially dynamic nature of Marx's work meant that it was not suitable for use as a simple textbook of revolutionary organization. According to Engels, in an 1882 letter to Eduard Bernstein (1850–1938), Marx's response to such use of his work was to say: "If anything is certain, it is that I myself am not a Marxist." Despite this, a vulgarized version of his thought became influential among socialist parties in Europe, and particularly in the powerful German Social Democratic Party under the leadership of Karl Kautsky (1854–1938), the so-called 'Pope' of Marxism (S. Hook cited in Morgan, 2003: 71). This was challenged by a revisionist wing of the German Social Democratic Party led by Bernstein, which emphasized the moral values of socialism rather than historical materialism. It also claimed cogently that in the advanced economies, such as Western Europe and North America, workers were being integrated peacefully into economy and society through parliamentary democracy, trade unionism, state welfare, technological advance, and a rising standard of living. The collapse of the Second (Socialist) International with the War in 1914 demonstrated the absence of effective solidarity among the workers of the world.

Lenin and Leninism

The Russian revolutions of 1905 and 1917 had a considerable impact on the socialist and communist movements internationally, not least by distinguishing between them. During the nineteenth century, Russia had experienced a variety of revolutionary socialist and anarchist movements, which were held in check by Tsarist autocracy. The emergence of a constitutional monarchy between 1900 and 1914 gave promise that Russia might develop economically and socially along Western European lines (McKean, 1977). In this context and with the failure of revolution in 1905, the Russian Social Democratic Party split over its ideological interpretation of Marxism. The *Mensheviki* (minority) argued that Russia could not expect a proletarian revolution until it had completed each historical stage of economic and social development as described by Marx. The *Bolsheviki* (majority), led by V.I. Lenin, argued that power could be secured on *behalf* of the proletariat through the so-called vanguard leadership of a disciplined and revolutionary communist party, organized according to what was effectively the military principle of *democratic centralism* in which decisions were taken by an authoritative leadership and carried out by disciplined rank and file followers.

This was Lenin's theory of the 'vanguard party,' the essentials of which are found in the classic pamphlet *What Is To Be Done? Painful questions of our movement*. It is a cogent handbook of revolutionary organization, a polemic written specifically for the struggle within the Russian Social Democratic Party, and first published in Germany in 1902. Its title echoed that of the political novel published in 1864 by the Russian radical N.G. Chernyshevsky (1828–89). Lenin argued that, as Western Europe and North America showed, the workers' movements were developing spontaneously as reformist organizations, exemplified by trade unions with their objectives of improving pay and conditions; achieving favorable legislation regarding welfare, health and safety, hours of work, and employment contracts; and supporting labor candidates for local and national political assemblies. The trade or occupational basis and reformist character of such workers' organizations also had the effect of emphasizing sectionalism, even the social stratification of the working class, which undermined solidarity and class consciousness. The consequence was the increasing incorporation of the workers into what Antonio Gramsci (1891–1937) was later described as the *hegemonic* system of welfare capitalism and parliamentary democracy. Lenin's revolutionary political solution, developed with the particular circumstances of Russia in mind, was that of the 'vanguard' communist party described above. It would be comprised of Marxist intellectuals and militants, whose task was to develop among the working masses a revolutionary rather than a *mere* trade union consciousness.

Lenin was to elaborate this in *Left-Wing Communism: An Infantile Disorder* (Lenin, 1968: 572–585) in which he argued that trade union and similar working class organizations were objectives to be secured in an ideological war of position. This again anticipated the work of Antonio Gramsci. It is shown also in Lenin's attitude toward cultural and educational development, exemplified in the ruthless and successful polemics against A.A. Bogdanov, *aka* Malinovsky (1873–1928), the chief communist advocate of an autonomous proletarian culture to be developed through the *Proletcult* movement. The quasi-philosophical disputes in which Lenin engaged should also be noted in this context, notably *Materialism and Empirio-criticism* of 1908. This was essentially a polemic directed against Bogdanov's ultraleft ideology and his claims to leadership of the Russian revolutionary socialists, rather than a systematic statement of Lenin's philosophical position. Lenin had set out his political ideas on cultural issues as early as 1905 in *Party Organization and Party Literature*, where he argued: "Literature must become … 'a cog and a screw' set in motion by the entire politically-conscious vanguard of the entire working class" (Lenin, 1971: 22–27). In his final article, published in March 1923, he focused on the obstacles to socialist development posed by an inadequate education system and a low level of general culture. He insisted on the maintenance of a vanguard élite when he argued: "Better fewer, but better. We must follow that rule" (Lenin cited in Morgan, 2003: 140).

It has been argued that the formation and installation in power of such a party oligarchy was Lenin's key contribution to communist political ideology, but one "… which has no solid foundation in the writings of Marx" (Shapiro cited in Morgan, 2003: 128). Such a party oligarchy would be responsible for administering the *dictatorship of the proletariat* through a control of economic base and ideological superstructure achieved by the monopoly of state power. This was elaborated further in *The State and Revolution* published crucially in 1917 (Lenin, 1968: 263–348). Lenin had developed a plan for revolutionary organization based upon his conspiratorial experience of politics in the repressive circumstances of Tsarist autocracy. In this sense, he followed Russian revolutionary practice. However, he was innovative in his objective of not simply destroying the Tsarist state, but of replacing it with a proletarian state, controlled by a vanguard communist party which would justify itself according to the later Stalinist slogan of 'Party and People are One!'

Lenin's other significant political contribution to communist ideology was his theory of imperialism. This was set out in *Imperialism: the Highest Stage of Capitalism* published in 1916 (Lenin, 1968: 169–262). Lenin argued that imperialism was a consequence of the increasing dominance of finance capital in the economy and of the subsequent need for capital to be moved in search of profits, increasingly difficult to obtain because of the relative stagnation of national economies. This led to multinational capital trusts and competition for world resources and markets. This had been anticipated by Marx and Engels in *The Communist Manifesto* when they wrote: "The need of a constantly expanding market for its products chases the bourgeoisie over the whole surface of the globe. It must nestle everywhere, settle everywhere, establish connexions everywhere" (Marx and Engels, 1986: 83). It is recognized that Lenin's analysis of imperialism as monopoly capitalism, and therefore capitalism in its final stage, was derived theoretically from Marx and empirically from Rudolf Hilferding (1877–1941), another Marxist, and from the English political economist J.A. Hobson (1858–1940), who had pioneered the economic concepts of underconsumption and unemployment.

The debate about imperialism is a complex one and continues within current international political economy. Here, we focus on the impact Lenin's theory of imperialism had on shaping Marxism–Leninism as the ideology of the Soviet Union and of the twentieth-century communist movement. Its key importance was that it allowed him to link revolutionary struggle among 'the toiling masses' of the undeveloped countries with that which he anticipated among the proletariat of the developed world, thus uniting in revolutionary consciousness both peasant and proletarian. This is important considering the uneven development of the Russian Empire, which became the USSR. It may be regarded as another distinct contribution by Lenin to the ideology of the communist movement in the twentieth century.

Leninism as a variant of Marxism was criticized severely by both anticapitalist revolutionaries and liberal democrats, most especially for its development of an élite vanguard Communist Party. For example, Rosa Luxemburg (1871–1919), the Polish communist based in Germany, differed from Lenin on both his interpretation of imperialism and his definition of the revolutionary party. She came to the orthodox Marxist conclusion that capital would only collapse once it had completed its own trajectory of growth. She maintained also that revolution could not be accomplished by command, but would come about through a spontaneous mass action that the united working class would be forced by worsening economic circumstances to undertake. As for party organization and the conduct of politics, she predicted that once the Bolsheviks had eliminated multiparty democracy and internal communist opposition, the so-called dictatorship of the proletariat would degenerate into the dictatorship of a faction and, ultimately, of that of an individual (Luxemburg, 1961). The anarchist Peter Kropotkin (1842–1921), following Mikhail Bakunin (1814–76), the arch opponent of Marx in the First International, considered Marxism, and its Leninist variant in particular, a centralizing authoritarian ideology. In *Communism and Anarchy*, Kropotkin argued that State communism was a contradiction in terms as: "… without freedom the whole structure of co-operation would collapse" (Kropotkin cited in Morgan, 2003: 129). Indeed, it has been argued by Schapiro that the autocratic rigidity of communism in the Soviet Union (and by extension to the international communist movement) can be traced to the socialist ideology and organizational methods first set out by Lenin as early as the period between 1899 and 1902 (Schapiro cited in Morgan, 2003: 128).

Stalin and Marxism–Leninism

The events of the Russian Revolutions of February and October 1917 are very well known. In 1918, the name Russian Communist Party (Bolshevik) was adopted at Lenin's initiative. It later became the CPSU, which in 1919 reinforced the organizational principle of democratic centralism by setting up a Politburo with its own Secretariat above the Central Committee of the Party. The state was administered in parallel fashion through a Council of People's Commissars appointed by the CPSU from among its own membership. In practice, the CPSU Secretariat controlled the appointment of Party officials to key appointments throughout the state apparatus, which put Stalin, as the General Secretary, in an exceptionally powerful position. The tolerance of debate and dissent within the Communist Party eroded rapidly, especially in the circumstances of the Civil War in Russia. The mutiny of sailors at Kronstadt was crushed in 1921 and at the 10th Communist Party Congress in the same year, factions such as the Workers' Opposition were banned. The treatment of the cultural heresy of the Proletcult has already been noted. By 1922, all other political parties had been banned.

Lenin had developed the vanguard party and led its seizure of power in Russia, an undeveloped and culturally backward country, with the aim of imposing the conditions for socialism. He saw the revolutionary potential of the Russian peasants and attempted to unite them with the proletarian socialist revolution. As we have noted, this strategy was criticized by such as Rosa Luxemburg and Georgi V. Plekhanov (1856–1918), who regarded themselves as orthodox Marxists. They believed that the conditions for socialism required certain necessary stages of economic development and could not be imposed as Lenin

believed. In practice, the contradictions of Lenin's policy resulted in the long-term maintenance of a one-party dictatorship that came under the control of the ruthless political organizer Joseph V. Stalin (1879–1953). In his massive book *Leninism* (1940a), Stalin describes the basic ideology and program, which he described formally as Marxism–Leninism, to be followed by the Communist Party of the Soviet Union under his direction.

In the pamphlet *Foundations of Leninism* (1940b), Stalin claimed that Lenin, although the follower of Marx and Engels, unlike them "… pursued his activities in the period of developed imperialism … when the proletarian revolution had already triumphed in one country, had smashed bourgeois democracy and had ushered in the era of proletarian democracy, the era of the Soviets" (Stalin, 1940b: 10). The basics of Marxism–Leninism were in place by the time of Lenin's death in 1924. The 'toiling masses,' proletarians and peasants, were to be united in a revolutionary political consciousness developed through the leadership of a communist party of militant intellectuals recruited for their political discipline, knowledge, and capacity for socialist theory. The revolution was to be accomplished in two stages. First, a 'dictatorship of the proletariat,' managed by the élite 'vanguard' communist party, would suppress counterrevolution, and ensure that natural economic resources and the means of production and distribution were in common ownership. Finally, communism would be achieved in a classless society in which Party and State would have 'withered away.'

How this would be achieved in practice remained inchoate and there continued criticism and dissension both from foreign communists and within the CPSU. Rosa Luxemburg has been mentioned, but she was murdered by reactionaries in 1919. Karl Korsch, another prominent German communist, and Georgy Lukács, a leading member of the Hungarian Communist Party, set out their concerns in exceptional theoretical works that attempted to recover the original dialectical and Hegelian philosophical basis of Marxism. Korsch's *Marxism and Philosophy* was published in 1923 and Lukács' *Marxism and Class Consciousness: Studies in Marxist dialectics*, which also contained an essay on 'The Marxism of Rosa Luxemburg,' in 1922. They aroused savage criticism from the Communist International or Comintern (see below) and in practice proved to be of little political importance, although reappearing as inspirations for the New Left in the 1960s. Korsch, a persistent critic of the Soviet Union and the Comintern under Stalin, was expelled from the German Communist Party in April 1926 and in 1936 went to the United States, where he died in 1961. Lukács, on the other hand, recanted his heresy and remained a functionary of the Comintern and a lifelong Marxist–Leninist. It should be mentioned that the Italian communist Antonio Gramsci, particularly his concept of hegemony, is often linked with Korsch and the early Lukács, and again was later an inspiration for the New Left. But Gramsci was in practice a convinced Marxist–Leninist charged by the Comintern with the task of Bolshevizing the Communist Party of Italy (PCI). Moreover, he was imprisoned in Italy from 1926 until shortly before his death in 1937. His work on culture, hegemony, and politics found in *The Prison Notebooks* (1971), although now very influential, only came into prominence some years after World War II.

Marxism–Leninism as Orthodoxy

After 1924, Marxist–Leninist ideology as interpreted by Stalin was consolidated as Communist Party orthodoxy both in the Soviet Union and through the Comintern. Stalin was well placed as Lenin's political successor to deal with internal Communist Party opposition to his authority. The main challenge came from Leon Trotsky (1879–1940), who had prestige because of the role he had played during the Kronstadt Mutiny (1921), in the signing of the Treaty of Brest-Litovsk (1918), and in the Russian Civil War (1918–21). Although in 1904 Trotsky had been a Menshevik, anticipating the fears of Rosa Luxemburg about the dangers of the Leninist party, by 1924 his political record marked him as a disciplined and ruthless Marxist–Leninist. He was however without a strong base of support in the CPSU and was unable to secure the publication of Lenin's so-called 'Last Testament,' dictated in December 1922, which had expressed doubts of Stalin's fitness to lead the Party. Trotsky was also in disagreement with Stalin over 'socialism in one country.' He believed that socialism in Russia could not survive without revolution in the advanced industrial countries, especially in Western Europe. He argued for 'Permanent Revolution' toward this objective in which the Comintern would of necessity have a crucial role. By 1925 Trotsky was removed as Commissar of War, in 1927 was expelled from the CPSU, and in 1928 was deported from Russia. He continued opposition to Stalin and to Stalinism from exile through a formidable output of polemics, but was murdered by a Stalinist agent in 1940. Trotsky's influence continued throughout the twentieth century, not least among the various components of the New Left.

By 1931, the Stalinist program based on this Marxist–Leninist ideology was virtually unchallenged within the Soviet Union. It regarded the working masses as so much raw human resource material, a commodity that could be shaped and used according to the central plan determined by the Communist Party bureaucracy. This reality was emphasized by Stalin in an address to the graduates of the Red Army Academy on 14 May 1935, when he said: "Cadres decide everything. That is the main thing now" (Stalin cited in Morgan, 2003: 143). The result in the Soviet Union, and indeed wherever else Marxist–Leninist communist parties came to power, was a state socialism, which claimed to be building toward an Utopian future. The means of production and of the allocation of wealth were state-owned, utilized through a central plan drawn up by the Communist Party and administered by the State. Thus, the economic base was said to be commanded on *behalf* of the working masses.

The superstructure of society, law, religion, culture, education, and opinion was commanded in a similar way by Party and State. For example, the Soviet State practised militant atheism, achieving an accommodation with the Orthodox Church only in the national emergency of the Nazi invasion of 1941. Marxism–Leninism was the core ideology in which the cadres of the Communist Party were trained in the numbers its rule required. Such cadres formed a bureaucratic apparatus, in Russian *nomenklatura*, according to the parallel structures of the Party and State. Their operational principle was 'democratic centralism'; and this determined policy and practice from the highest Party and State organs to local production units and

house committees, and strengthened the hegemony of the Communist Party over everyday Soviet life.

The economic objective was the building of 'socialism in one country.' Stalin introduced a succession of *Five Year Plans* between 1928 and 1942 and collectivized agriculture, which consolidated the command economy in the Soviet Union. This, together with the Soviet Union's immense natural resources, made it one of the largest industrial powers in the world. The average annual growth rate for these years has been estimated at 10%, which is exceptionally high. The emphasis was on building the foundation for further industrial growth accomplished; using State power ruthlessly; through a massive increase in the labor force; and at the expense of agriculture, private enterprise, and consumption and general welfare. It is probable that without the industrialization of the Five Year Plans, the Soviet Union would not have been able to defend itself against the Nazi invasion of 1941, with consequences for the outcome of World War II in Europe.

In *Foundations of Leninism*, Stalin had declared confidently: "The combination of the Russian revolutionary sweep with American efficiency is the essence of Leninism in Party and state work" (Stalin, 1940b: 112). There were two further Five Year Plans after 1948, which concentrated on making good the industrial losses of the War years, again at the expense of consumption and general welfare. This is not the place to describe or analyze the enormities that accompanied this process of forced industrialization and of modernization through labor conscription, the destruction of a legal system independent of the administrative apparatus, and a repressive ideological hegemony leading to political purges and labor camps, again enforced by the State and its police system. This is now very well documented, for instance, by Robert Conquest (1990) and, from the inside by one of its countless victims, Alexander Solzhenitsyn (1988). The withering away of the Party and the State had become a lost horizon, an Utopian chimera of history.

Marxism–Leninism and International Communism

World War I was seen by Marxist–Leninists as proof of Lenin's *Imperialism: the Highest Stage of Capitalism* (1916). It was argued that the War would lead to the destruction of capitalism through international proletarian revolution. This echoed the final words of *The Communist Manifesto*: "Working Men of All Counties Unite!" Such unity would, it was believed, lead to a world socialist system, based on equality and fraternity, which would agree on the basic issues concerning resource allocation and be free of national prejudices, racism, and militarism. Lenin argued that the Second (Socialist) International had betrayed socialism when it collapsed on the outbreak of War and he was alarmed at efforts to revive it in 1919. In response, he organized the Communist or Third International (Comintern) in March 1919 with the object of promoting world revolution. As Stalin claimed later, the struggle against "the opportunism of the Second International" was to be "one of the most important tasks of Leninism" (Stalin, 1940: 11).

The Comintern was established as a single world communist movement with the national communist parties forming its affiliated 'sections' according to Twenty-one Conditions for membership. Essentially, each section was required to organize on the same Marxist–Leninist ideological basis as the CPSU, the dominant party. Indeed, as the post-War prospects of revolution elsewhere than in Russia receded, so the strategy and tactics of the Comintern reflected the internal struggles and purges of the CPSU. For example, in 1927 Trotsky was inevitably expelled from its Executive Committee when expelled from the CPSU. The national communist party sections were also expected to adapt to often drastic changes in direction according to the perceived aims of Soviet foreign policy. The swings from the *Popular Front* of 1935 to the *Nazi-Soviet Non-Aggression Pact* of 1939 and back again with the German invasion of Russia in 1941 are egregious examples. The Comintern was dissolved in May 1943 in the context of the Allied coalition against Nazi Germany.

After World War II, the Red Army's occupation saw Marxist–Leninist communist parties installed in power in much of eastern and central Europe. These were 'satellite' parties of the CPSU, with the exception of socialist Yugoslavia and Albania. The Comintern was replaced by the Cominform in 1947, with the *Council for Mutual Economic Assistance* in 1949 and, of course, the military alliance of the *Warsaw Pact* in 1955. These provided a common platform of politics, economics, and security for the members of the Soviet bloc. It had an influence extending beyond Europe to the developing world, for example, in socialist Cuba and Vietnam, and as the Soviet Union tried to engage with so-called nonaligned countries. However, once again the essential aim was to serve Soviet foreign policy, rather than the goal of world revolution. These organizations were themselves dissolved in the 1990s with the collapse of the Soviet bloc and of the Soviet Union itself.

However, during the Cold War with the capitalist West, Soviet Marxist–Leninist ideology was often accompanied by the use of force, as in Hungary in 1956, in Czechoslovakia in 1968, and in Afghanistan in 1979; and through proxy conflicts such as those in Korea, Cuba, Angola, Mozambique, South Africa, and Vietnam. Indeed, Marxism–Leninism had a very influential role throughout the old Third World during the twentieth century. It was an inspiration for national liberation movements, for example, in Latin America, especially Cuba, where Fidel Castro (1926) and Ernesto 'Che' Guevara (1928–67) became revolutionary icons; in Chile, where the Communist Party, supported by prominent intellectuals such as the poet and Nobel Prize laureate Pablo Neruda (1904–73), was a key component of the Popular Unity government of the Marxist and Socialist Party leader Salvador Allende (1908–73) deposed by military coup d'état in 1973; in Southeast Asia, where the Vietnamese communists, led by another revolutionary icon Ho Chi Minh (1890–1969), inflicted decisive military and political defeats on the French and later on the Americans; and in South Africa, where the Communist Party, led by other iconic leaders such as Joe Slovo (1926–95) and even it is claimed Nelson Mandela (1918–2014), allied with the African National Congress in the antiapartheid struggle.

Despite these significant local successes, ideologically there was a retreat from belief in the inevitability of imperialist war as capitalism showed it could adapt to the end of empire. There was also nuclear weapons technology, which invalidated possible gains from direct armed conflict. Marxism–Leninism

turned to the theory of state monopoly capitalism as an alternative, but this implied that Lenin's theory of imperialism had been overtaken by events. The goal of world revolution was also to become a lost horizon of Marxism–Leninism, another Utopian chimera of history, whatever official Soviet texts may have said (Volkov, 1982).

The *Eurocommunism* phenomenon of the 1970s and 1980s is a further example. This was an attempt, notably by the Italian Communist Party (PCI) and the Spanish Communist Party (PCE), to develop a strategy relevant to contemporary Western Europe and not tied to the Marxist–Leninist orthodoxy of the CPSU. The phenomenon was influenced by a growing interest in the Gramscian concept of hegemony. Ideologically, it symbolized the growing divisions between communist revisionists and doctrinaire Marxist–Leninists, and was mentioned by Mikhail Gorbachev as an influence on his own political thinking. However, the large French Communist Party (PCF), apart from a brief period, and a number of smaller parties remained opposed to Eurocommunism and stayed in accord with the CPSU until the end of the USSR.

Mao Zedong Thought and Marxism–Leninism

Given the continuing impact of the Communist Revolution and People's Liberation in China in 1949, it is necessary to say something briefly about the relationship between Mao Zedong Thought and Marxism–Leninism. It should be noted that there are several points of difference between the Chinese and the Russian revolutions. The former was overwhelmingly a peasant revolution, successful only after a long guerrilla war against both foreign (imperialist Japanese) and domestic (nationalist *Kuomintang*) enemies. In such circumstances, Mao Zedong (1893–1976), the leader of the Chinese Communist Party (CCP) laid down a *mass-line*, which argued that all power and authority is derived from the will of the people and must be endorsed by them, through mass meetings and popular demonstrations. It emphasized also that officials and intellectuals, especially those within the Communist Party, should be monitored consistently and called to account regularly. This would prevent the growth of privileged hierarchies and ensure that revolutionary momentum was sustained. The ideological essentials of this *mass-line* were set out in Mao Zedong's now famous *Talks at the Yenan Forum on Art and Literature* in May 1941 (Mao, 1954: 63–93). They anticipated dramatic later Chinese revolutionary episodes such as the *Great Leap Forward* (1958–59) and especially the *Great Proletarian Cultural Revolution* (1965–69).

That said, Mao Zedong constructed the CCP according to Marxist–Leninist organizational principles and considered himself to be applying the basic tenets of the ideology to the specific conditions in which the CCP found itself. One is reminded of Marx's comment in *The 18th Brumaire of Louis Napoleon* cited above. Mao Zedong was not fundamentally a sophisticated theoretician, but he was a revolutionary tactician and a ruthless political mobilizer of genius, who inspired Maoist or quasi-Maoist groups elsewhere such as the *Naxalites* in India, the *Sendoro Luminoso* or Shining Path in Peru, and the *Khmer Rouge* in Cambodia. It has been said that Marx provided the philosophical basis of communism, Lenin its political organization, and Mao Zedong the guerrilla warfare strategy necessary for an extended revolutionary war. However, there is now virtually nothing left in contemporary China of Maoism with its égalitarian rejection of bourgeois values, other than memories of the enormities of the Cultural Revolution, although the People's Republic itself remains Mao Zedong's achievement. The CCP retains its Marxist–Leninist organizational structure of democratic centralism, but in the service of what is essentially an authoritarian and indeed nationalistic state capitalism.

Conclusion

The outcome of World War II raised hopes that the system of economic and of ideological controls, developed during forced industrialization and total war, might give way to something more open and flexible. In practice, aggravated by the onset of the Cold War, Marxist–Leninist ideology continued to hold that the world had two camps, that of the capitalist imperialists and that of the socialists and democrats who were building communism. In the Soviet Union, this was reasserted to ensure ideological conformity in literature, music, the creative arts, education, and the sciences. It should be noted that the last had for pragmatic reasons been relatively exempt from such ideological control. This campaign, intended to control those capable of constructing ideological alternatives, was enforced by A.A. Zhdanov (1896–1948), probably on the specific instruction of Stalin himself, and was known in Russian as the *Zhdanovschina*. The most notorious example was the official support for Trofim D. Lysenko (1898–1976) and his ideological version of genetics. Although this campaign eased following the death of Stalin in 1953, such ideological direction of the intelligentsia became associated increasingly with efforts to control prominent dissidents such as the authors and Nobel Prize winners Boris L. Pasternak (1890–1960), Alexander I. Solzhenitzyn (1918–2008), and the nuclear physicist Andrei D. Sakharov (1921–89). This may be compared with the triumphal reception accorded to the award of the 1965 Nobel Prize for Literature to the socialist realist novelist Mikhail A. Sholokhov (1905–84).

The long post-War retreat of Marxism–Leninism as an ideology may perhaps be dated from the occasion of the condemnation of Stalin by Nikita S. Khruschev (1894–1971) through his so-called 'secret speech' *On the Cult of Personality and Its Consequences* to a closed session of the 20th Party Congress of the Communist Party of the Soviet Union on 25 February 1956. The speech drew attention to Stalin's purges of the Soviet military and Communist Party cadres, especially in the period leading up to World War II. Khrushchev explained these as a consequence of Stalin's personality cult and as a betrayal of Marxism–Leninism, rather than as something inherent in the system. It was prompted by struggles within the CPSU, but also marked the beginning of a long ideological thaw and the eventual breakup of the Soviet system. The speech became widely known, although it was only published officially in 1989.

The years subsequent to Khrushchev saw the Marxist–Leninist system come increasingly under strain, both within the Soviet Union and externally, with the period of Leonid Brezhnev (1906–82) especially stagnant, the *Brezhnev Doctrine*

(1968) being essentially defensive. However, revisionists believed the system could still be revived from within. In March 1985, Mikhail S. Gorbachev (1931) was selected as CPSU General Secretary, becoming the first president of the Soviet Union in 1990 (when he also won the Nobel Peace Prize). Gorbachev attempted reform through a twin policy of *perestroika* (restructuring) and *glasnost* (openness). It was supported by a revisionist Party intelligentsia and encouraged by a slowly emerging *civil society* (a concept anathema to doctrinaire Marxism–Leninism).

It proved too little, too late as the Soviet system, together with those of its satellites in eastern and central Europe, imploded. It is important to note that this process had been long and drawn-out as a reservoir of support for the Marxist–Leninist system persisted, as did its outposts elsewhere in the world. Nevertheless, on 26 December 1991, the USSR was dissolved formally and Marxism–Leninism was effectively moribund as a political movement. However, its influence internationally was considerable as the history of the twentieth century shows. The question whether Marxism continues to be influential is quite another matter as, for example, the continuing use of dependency theory and of historical materialism in the debates of international political economy also shows.

Marxist Approaches to Social Work

Tom Vickers, Northumbria University, Newcastle, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores the diversity within Marxist approaches to social work, outlining key aspects of Marxism and the implications for social work under capitalist states, in situations where states break down, and under socialist states. Within each of these contexts, key examples are explored to demonstrate the range of approaches taken. The article argues that there has been a neglect in the English-language literature of Marxist approaches to social work under socialism, and suggests that recent moves to open up the definition of social work through the concept of 'popular social work' offer one approach to begin filling this gap.

Introduction

English-language writing on Marxist social work has generally been limited to the 'Radical Social Work' (RSW) tradition (e.g., Corrigan and Leonard, 1978; Reisch and Andrews, 2001; Lavalette, 2011) and has neglected much of the diversity within Marxism including the experiences of socialist countries (the limited English-language literature includes Oanh, 2002; Strug, 2006; Yip, 2005). A comprehensive coverage of Marxist approaches to social work is beyond the scope of this article. Instead, the author outlines the key features of Marxist understandings of society and the implications for social work under capitalist states, in situations where states break down, and under socialist states. Within each of these contexts, key examples are explored, following Marxism's attention to concrete conditions. The article is written from a Marxist, specifically Leninist, perspective. The author has attempted to give a fair account of other trends, and be open about his standpoint to support a critical engagement.

Marxist Understandings of Society

> Marxism is many things…in a state of flux and development, and is subject to highly divergent interpretations…Marxism is not simply a theory: it is a political practice which confronts capitalism with an alternative model of a social order. (Corrigan and Leonard, 1978: pp. xiii–xiv)

Marxism is unfinished, containing theory and practice in a dialectical unity, 'praxis' (Lenin, [1895–1916]1972: p. 103). Marxism presents a systemic view that can help social workers relate the personal to the social to address the root causes of people's problems, an aim shared by some feminist and anti-racist approaches.

Dialectical Materialism

The Marxist analytic method, dialectical materialism, involves an iterative movement from holistic and concrete living phenomena to a 'number of determinant, abstract, general relations' and from there back to a more complex understanding of the living whole (Marx, [1857]1973: pp. 100–102). Marxism focuses on the shaping of consciousness by experience, shaped in turn by the way society is organized, with its most basic roots in processes of production and reproduction. Marxism's central premises are that people must produce to survive, that the satisfaction of needs leads to further needs, that people reproduce not only themselves but their species, and that all this activity is organized socially, depending on the means of production available. Dialectical materialism is distinguished from crude materialism by its acknowledgment that history is determined by not only the economic class struggle, but also "the legal, political, religious, artistic or philosophic – in short, ideological forms in which men (sic) become conscious of this conflict and fight it out" (Marx, [1859]1971: p. 21), with ideas impacting back on the future development of the material basis of society. In one example of the application of this to social work, Corrigan and Leonard (1978: pp. 129–132) suggest that migrant families within Britain can be better understood in the context of the relations of production in their country of origin, and how these interact with relations of production within Britain. Such understandings enhance agency by developing an understanding of how structural conditions shape and limit individual behavior.

Class Struggle

Marxism is not the only approach focusing on class, but Ferguson (in Lavalette, 2011: pp. 128–129) distinguishes Marxism by its attention to inequalities in the ownership of the means of production, as opposed to simply in distribution, and exploitation as opposed to simply domination, with the contradictions and consequent struggle between exploiters and exploited driving the development of society.

In some cases, racialized, gendered, and other forms of oppression have been neglected by Marxists, subsumed within a homogenous view of the working class that is implicitly white, male, heterosexual, in paid employment, and able-bodied, and critiques of this neglect have contributed to more complex understandings of class (e.g., Dixon et al. in Craig et al., 1982; Meagher and Tett in Cooke and Shaw, 1996). However, this neglect is not fundamental to Marxism. Anderson (2010) shows that Marx himself devoted considerable attention to 'race,' and many Marxists have

continued in this tradition. For example, Chandler Owen, the recipient of one of the first social work fellowships in the United States, linked capitalism to racism, supported unionization of black labor, and was the leader of the Political Council, which was the only African-American political group to come out in support of women's suffrage (Reisch and Andrews, 2001: pp. 44–45). In a long-running debate within Marxism, Clough (1992) argues that the sidelining of 'race' and gender within some approaches to Marxism reflects the narrow interests of a minority of predominantly white, male, and 'skilled' workers in capitalist countries, who are afforded relative privileges on the basis of their countries' imperialist position in the global economy, receiving super profits from the exploitation of the workers and resources of oppressed countries (Callinicos (2009) gives an opposing view).

The Politics of Social Work

Marxism suggests that social work is inherently political:

> conventional practice is fully political, whether or not its politics are acknowledged. The ends it serves, however, are conservative ones. Radicals do not seek to introduce politics into an apolitical situation. Rather we mean to challenge the politics of compliance and to introduce the politics of resistance and change. (Galper, 1980: pp. 10–11)

For example, Lavalette and Ioakimidis (2011: pp. 142–146) point to the political role of the US-backed international expansion of social work in Western Europe and Asia following the Second World War as part of the Marshall plan, "the goal of which was to make the countries 'safe' for Western capitalism and establish a social and political bulwark against Communist expansion," first through the United Nations Reconstruction and Rehabilitation Agency and then the American Rehabilitation Missions. Similarly, the first professional training programs for Nicaraguan social workers were established in the early 1960s, following the Cuban Revolution "to promote a model of development in the region intended to reduce social discontent and prevent further such revolutions" (Wilson and Hernández in Lavalette and Ioakimidis, 2011: p. 77). In such a context, for social workers to fail to consciously adopt a political position leads to tacit complicity with the status quo, which serves the interests of the dominant class.

The State

Marxists differ in their understanding of the capitalist state, its capacity for reform, and if it must be abolished then what should replace it. They agree in viewing the class character of the state as important in creating the conditions under which social work operates. Lenin ([1917]1972: p. 8) defines the state as an institution emerging in the midst of class struggle as a means of holding in check irreconcilable antagonisms to stabilize the system. In this view, the state emerges as the organ of the most powerful, economically dominant class, who, through the exercise of a state apparatus specifically tailored to its needs, maintains itself as the politically dominant class within a given geographical territory (Lenin, [1917]1972: pp. 13–14). Another important Marxist theorist of the state, Gramsci ([1929–1935]1982), analyzed the dialectical relationship between consent and coercion in the modern capitalist state, and has been particularly influential within Western academia. Disagreements with the Leninist conception of the state typically concern arguments that the British state enjoys 'relative autonomy' from capitalist pressures; is neutral with regard to different sections of society; is fought over by competing interest groups; or is not coherent, with different interests served by different sections of the state. The latter argument has been associated historically with the Fabians in the British Labour Party, who differentiate between a 'good' side of the capitalist state, including social services, health, education, and nationalized industries, and a 'bad' side, including defense, law, and order, and aid to private industry (LEWRG, 1980: pp. 52–53).

Among Marxists who understand the capitalist state as irredeemably antiworking class, there is a divergence between 'libertarian' or 'autonomous' trends, which reject any kind of state, and those who argue a socialist state is needed to facilitate a transition to a classless society. Within the latter, there is a further division as to what constitutes socialism, with different Marxists categorizing the same states as 'socialist,' 'state capitalist,' or 'degenerate/deformed workers' states' (Galper, 1980: pp. 29–39). The class character of the capitalist and socialist states implies a need for a different kind of social work under each. This is connected to

- Socialism's claims to overcome the root causes of the social problems social work seeks to address rather than simply manage their consequences (Strug, 2006);
- The role of socialist state, political and 'mass' organizations in tackling the same issues social work seeks to address (Oanh, 2002);
- Contradictions between professional ideals of individual autonomy and socialist ideals of collective political leadership (Ngai, 1996).

It is a point of contention in the historiography of social work whether social work was unnecessary in countries attempting to build socialism because the problems it sought to address did not exist, at least not to the same extent as under capitalism, or whether the existence of those problems was simply denied by political leaderships lacking in reflexivity, or whether social work continued under socialism, but in different forms and with different personnel (Ngai, 1996: p. 293). The reality may be a mixture of all the three, in different measures in different countries at different times.

Social Work under Capitalism

Because Marxism poses a threat to the capitalist state, for social workers to openly declare their Marxism may jeopardize their employment and with it their ability to practice Marxist social work. Although Marxist social work academics often have greater freedom than practitioners, there has still been a tendency to avoid explicitly discussing their underlying Marxist method. The *Critical and Radical Social Work* journal

launched in 2013 is typical in not mentioning Marxism in its title or aims despite being edited by committed Marxists. The most public face of Marxist social work under capitalism has been as an influential strand within the RSW tradition. In the United States, Reisch and Andrews (2001) trace RSW's history back through the Rank and File Movement of the 1930s, led by Marxists such as Bertha Reynolds, who "warned that unless New Deal policies moved beyond 'offering palliatives to assuage the miseries of poverty and racism,' social workers would do little more than 'carry out the designs of the ruling class and victimize clients'" (Reynolds cited in Reisch and Andrews, 2001: p. 79). Similar histories exist in other countries, such as the East London Federation of Suffragettes, founded in Britain in 1914 by the communist Sylvia Pankhurst, which organized cost price restaurants, nurseries, and other services alongside political agitation. In the 1970s, economic crisis increased antagonisms between the state and service users in some countries, prompting a growth in RSW including a practitioner movement around the *CaseCon* manifesto and magazine in Britain; organizations such as 'Inside Welfare' in Australia; publications such as Galper (1980) in the United States; and Bailey and Brake (1975) and Corrigan and Leonard (1978) in Britain. The history of RSW is contested, seen as either dying out with the defeat of working-class struggles in the 1980s (Langan and Lee, 1989) or developing into antiracist, black, and feminist approaches in response to Marxists' failure to respond adequately to racism, sexism, and other forms of oppression that intersect with class (Dominelli, 1986, 1988; Dominelli and McLeod, 1989). In the early twenty-first century, RSW returned to prominence as a distinct approach, with publications such as Lavalette (2011) and the founding of the Social Work Action Network in Britain, connected to similar organizations in countries as diverse as Hungary, Japan, and the United States (Lavalette and Ferguson, 2011). The discussion here will focus on Britain and the United States, both because they have a more extensive English-language RSW literature and because of their impact on RSW internationally. In Britain, a complicated history between social work and community work led to a distinct strand of 'radical community work' (e.g., Craig et al., 1982), part of social work in many countries, and this branch of the tradition offers important contributions that are included here. The author focuses on the more or less explicitly and self-consciously Marxist elements within RSW, while acknowledging Marxism's wider impact, including within service user movements that have developed alongside RSW (Beresford in Lavalette, 2011: pp. 96–97), and recognizing that many social work writers draw on Marxism without explicitly discussing Marxist theory.

The central problem driving the development of RSW is the contradictory character of capitalist state welfare, simultaneously ensuring a healthy and compliant workforce, managing the behavior of the working class (including attempts to undermine resistance to exploitation), and also providing important material resources for working-class people that often represent concessions won from the capitalist class through hard struggle. Jones and Novak (1999: pp. 79–80) point out, as many others within RSW have done, that state social work interventions are almost exclusively targeted at the poorest in society, who have 'the most marginal if any relationship to waged labor' and who are therefore regarded by the capitalist class as a surplus population to be managed. Stevenson (1978) suggests that while elements of service and control are inherent in all areas of 'human services,' including social work, the balance is different for different groups, with the example that

> the service aspect is dominant in New York City schools when teachers teach white middle-class students. The control aspect is dominant when they teach black and Latino working-class students. (Stevenson, 1978: p. 459)

In a concise article that moves beyond many of the classic social work texts in its treatment of the political economy of welfare work, Stevenson (1978: pp. 457–459) argues that 'human services' labor represents production of a special kind, involving direct contact between producer and consumer that opens up possibilities for solidarity through human contact but operating in a context where there is a material incentive for human service workers to maintain dependency among service users to ensure continuing demand for their 'product.' While Marxists are not alone in arguing that dependency is avoidable, Marxist approaches offer an explanation of the tendencies within capitalist state welfare that pull social workers in contradictory directions, to side with service users in a struggle to overturn the basis of their oppression, requiring at times a willingness to confront the capitalist state, and to cooperate with the state in managing service users' responses to their oppression within limits that will not disrupt the fundamental structures of capitalist society.

There has been a divide within Marxist social workers over how to respond to the contradictions outlined above, centered on whether social work is simply a mechanism of social control, with little or no potential to contribute to progressive change, or whether there is potential to subvert ruling class priorities for social work and develop progressive practice within the capitalist state. RSW has predominantly represented the latter perspective, informed by an understanding of the state as 'semiautonomous' (LEWRG, 1980), containing contradictions and reflecting the class struggle and the balance of forces at a particular point, and therefore capable of shifting its priorities in response to pressure from a strong and organized working class. This implies spaces within the state, created by the class struggle, for socialist practice, which can in turn support further advances in the class struggle. RSW theorists such as Corrigan and Leonard (1978: p. 106) and Jones and Novak (1999: pp. 154–155) point out that compared to civil servants or employees of large state bureaucracies, social workers, and other welfare professionals have a degree of autonomy in their day-to-day work that makes it difficult for the state to monitor and control them, even if this autonomy has been reduced in many countries through increasing bureaucratization of social work and closer supervision (Garrett, 2009).

Some Marxists argue the aims of RSW should not focus on solving individuals' problems, but on highlighting the contradictions that they demonstrate and raising political consciousness about their wider causes as a basis for forming

alliances that could achieve structural change (Cooke in Cooke and Shaw, 1996: pp. 6–25). This approach calls for education alongside organization, recognizing that "the development of a fuller political analysis can only be achieved by the introduction of systematic reflection and more structured educational opportunities within the community work process" (Cooke in Cooke and Shaw, 1996: pp. 20–21). Others argue that there is not necessarily a contradiction between Marxist social work and meeting immediate needs, but rather that RSW needs to link the personal and immediate with the collective and the long term:

> If counselling is required, it must be provided. But if…counselling…fails…to link…temporary and partial solutions with the larger social transformation that is required for realistic solutions, then it is extremely limited, at best, and deceptive and repressive, at worst. (Galper, 1980: pp. 12–13)

Following this approach, standard processes of referral might be reinterpreted to include workers "investigating appropriate political resources in the community and determining their relevance to the particular issues faced by those with whom we work" (Galper, 1980: p. 137). RSW advocates have argued that as well as more overtly political activities, such as political education and organizing, social work also has an important role to play in supporting people to sustain their involvement in collective struggle. For example, Bailey and Brake (1975: pp. 9–10) argue for the need to help people overcome the 'psychological damage' that may result from resisting capitalist hegemony. Baldock (in Craig et al., 1982: p. 30) draws on work with single parents to argue that RSW can foster strong mutual caring to support political activity by sections of the working class who are normally excluded from political activity by the pressures of their personal circumstances.

Questions regarding the relative importance of workplace and community struggles, and the relationship between them, have been contested within RSW. This reflects a contradiction between the emphasis on trade union struggles within dominant trends in the broader Marxist movement in countries such as Britain, Canada, and the United States, and the daily contact between social workers and sections of the working class facing oppression outside the workplace, and at times engaged in significant struggle there, such as the movement against the Community Charge, known popularly as the 'Poll Tax,' in Britain in the late 1980s and 1990s. Corrigan and Leonard (1978: pp. 142–147) are typical of the dominant trend in the wider Marxist left in these countries when they interpret an alliance between social workers and the working class as meaning "the trade unions must come into the forefront of all those involved in campaigns against the welfare cuts at a local and national level," because "they represent the only powerful force that has struggled and will continue to struggle against the cuts in the welfare state." The authors acknowledge the existence of only two trends within Marxism on the question of trade unions, both of which assert that trade unions must be the preeminent working-class organizational form, and differ only on the emphasis placed on the rank and file versus the leadership. This view neglects the work of Marxist theorists such as Lenin ([1917]1972) and Gramsci ([1929–1935]1982) who have written extensively on the limitations of trade union politics and the potential for their co-option by the ruling class. Corrigan and Leonard note the limitations of unions, which "by themselves (they) are not revolutionary or potentially revolutionary organisations of the working class," but argue this has a historical and cultural, but not material, basis, and can therefore be changed through a long period of persuasion (pp. 142–147; for an alternative view on British trade unions see Clough, 1992). Stevenson (1978) points to the dual character of human service workers' role as both oppressed workers and agents of oppression toward other working-class people, which creates the potential for a material divide between the immediate material interests of social workers represented by their trade unions and the interests of other sections of the working class using their services, so that

> certain struggles of progressive elements among human service workers (i.e. those around traditional bread-and-butter issues such as higher salaries and better working conditions, as well as more fundamental struggles around democratization and control) may not have any bearing on their role as oppressors. (Stevenson, 1978: p. 460)

In a recent example, in June 2013, Britain's biggest public sector union, Unison, issued a circular to branches instructing its members to implement a cut to rent payments for social housing tenants assessed as having one or more unused bedrooms, popularly dubbed the 'bedroom tax,' lest Unison members jeopardize their employment.

Some RSW writers place greater emphasis on organizing outside unions. Galper (1980: pp. 198–212) considers possibilities for organizing with other social workers inside and outside unions, where possible with other workers sharing 'socialist commitments.' Cooke (in Cooke and Shaw, 1996: p. 11) argues that, although building links with the trade union movement and Labour Party were central to the aims of many radical community workers in Britain in the 1970s, this was often not achieved in practice, and cites factors including the often 'lukewarm response from Trade Union representatives' and the fact that many community campaigns of the period were forced to confront Labor governments and labor-controlled local authorities. Fleetwood and Lambert (in Craig et al., 1982: pp. 48–58) discuss the disconnect between socialist community workers' experience of housing struggles, in particular from 1975, and the orthodoxy of socialist practice in Britain, which "scorned nonworkplace struggles" and "exhorted activists to link up with trade unions and trades councils in the muscle of the labor movement," even in a period where "the very existence…of a labour movement can be seriously doubted" (Fleetwood and Lambert in Craig et al., 1982: p. 49). Accusations of neglect of racism and sexism also contributed to the fragmentation of struggles in and against the state. Fleetwood and Lambert argue that the lack of engagement between socialist community workers and

community struggles lead to the left critique of the limits of spontaneous community action becoming a self-fulfilling prophesy, since

> divorced from socialism, denied legitimacy by the labour movement, such work has tended to be small-scale, cautious, uncoordinated and individualistic. (Fleetwood and Lambert in Craig et al., 1982: p. 50)

Against this, the authors propose a form of socialist practice that

> starts and grows with the experience of people in struggle…developing techniques, organisational forms and relationships which recognize the personal barriers (constructed by capitalist society) to a class consciousness…it will entail people to do extraordinary things, to dress up, sing songs, perform antics in council chambers, to travel unprecedented distances. (Fleetwood and Lambert in Craig et al., 1982: p. 57)

This history of debates within RSW can be drawn upon to inform social work practice today.

Social Work Where the State Breaks Down

Lavalette and Ioakimidis (2011) use the term 'popular social work,' encompassing welfare activities provided by communities and social movements, including situations where states break down or are unable to cope, whether as a result of war, revolution, or natural disaster. There is a rich tradition of welfare services as part of anticapitalist struggles, dating back to Karl Marx, who organized committees to support fellow German refugees after his arrival in London in 1848. The most significant international efforts include the International Organisation for the Support of Fighters for the Revolution (MOPR), known in many countries as International Red Aid, founded in 1922 (Schilde in Hering and Waaldijk, 2003: p. 140), and Cuba's internationalism in education, sport, and health care since 1959 (Yaffe, 2009). MOPR supported communists imprisoned, injured, or killed in the course of political activity, together with their families, through "legal counselling, social welfare for prisoners (including cash, clothing and food for their families), children's homes, support for campaigns directed at the liberation of communist political prisoners and support for political refugees" (Schilde in Hering and Waaldijk, 2003: p. 144). Red Aid activities varied from country to country, and sometimes went far beyond support for political prisoners, for example, in the early 1920s the Swiss section provided free contraceptives and advice (Hering in Hering and Waaldijk, 2003: p. 91).

Welfare activities were also organized by communists during periods of revolutionary warfare, for example,

- from the 1930s the "patriotic and revolutionary Vietnamese tried to build networks of youth, students, workers (horse-cart drivers, carpenters, shoe-makers, porters) in the form of 'red relief services' to serve the poor and provide mutual assistance" (Oanh, 2002: p. 85);
- from 1940 to 1944 in Greece, under Nazi occupation the communist-led EAM (*Ethniko Apeleftherotiko Metopo*, trans. National Liberation Front) developed welfare provision based on grassroots democracy and solidarity, encompassing "the fight for survival, popular administration and 'holistic development'" (Ioakimidis in Lavalette and Ioakimidis, 2011: pp. 115–132).

Social Work under Socialism

The author uses the term socialism to represent a method for organizing society rather than a blueprint for utopia, characterized by social ownership of the means of production, a high degree of democratic participation, and prioritization of quality of life and conditions for each individual to flourish (Galper, 1980: pp. 29–39). The characterization of countries as socialist is widely contested, but has included countries in Africa, Asia, Europe, and America (Galper, 1980: pp. 29–30). The limited literature that exists on social work under socialism shows the diversity of approaches and suggests there would be much to be gained from further research in this area, illustrated by the following brief case studies of the changing role of social work in China and Cuba.

In China, professional social work was abolished in the 1950s along with other social sciences that were judged unsuited to socialism because they developed under capitalism. Ngai (1996: p. 292) argues that professional social work's reemergence in the 1980s was driven by social problems consequent on China's transition to a market economy. During the socialist period, social work took fundamentally different forms within the context of a wider revolutionary process aimed at advancing human welfare. Ngai (1996: p. 293) describes a range of organizations playing 'social work service' roles, including the Ministry of Civil Affairs and mass organizations such as the All-China Federation of Trades Unions, the Chinese Communist Youth League, the All-China Federation of Youth and the All-China Federation of Women. There is also a strong resonance between social work and health care developments during the Cultural Revolution from 1964, which aimed to generalize medical knowledge to the whole population through the 'barefoot doctors' movement, equipping people with the skills to care for themselves and one another, alongside advances in professionalized specialist care. In mental health care, there was a movement in the early years of the Revolution away from institutionalization and medical approaches to a range of individual and collective approaches focusing on rehabilitation wherever possible, the abolition of restraint and combining Western and Chinese practices developed under capitalism with new methods including therapy through productive work and other activities (Yip, 2005: p. 108). During the Cultural Revolution, the political character of psychiatric treatment was intensified, with mental illnesses viewed as inseparable from the damage done to individuals by capitalism. Forms of treatment included mutual support between patients; 'self-reliance,' meaning that patients should be actively engaged in investigating their conditions and understanding their treatment; political education classes, led by a patient member of the group; and open self- and mutual-criticism. Critics argue that psychiatric

confinement was also used during this period as a political weapon against opponents of the Revolution's leadership (Yip, 2005: pp. 108–110).

In Cuba, in the first few years after the 1959 revolution, mass organizations took on social work roles. For example, the Cuban Federation of Women described its members as 'empirical social workers,' who

> facilitated the entry of women into the labor market, promoted their economic, political and social involvement with the Revolution, and organized community members for participation in major educational and public health initiatives. (Strug, 2006: pp. 751–752)

When professional social work was reintroduced, through technical training institutes from 1973, it was as assistants to health care workers (Strug, 2006: p. 752). In the 1990s, the extreme hardships of the 'special period' following the collapse of the Soviet Union, the tightening US blockade, and social problems fueled by the reintroduction of tourism such as drugs and prostitution, led social workers to target particularly at-risk sections of society, including pregnant women and older people. These social workers became increasingly involved in the People's Councils that were intended to act as a bridge between municipalities and local communities, 'comprising community delegates, mass organizations, and administrative entities,' while also maintaining strong links to medical practitioners and the Communist Party (Strug, 2006: pp. 753–755). Social workers engaged in community organizing, built community members' capacity to participate in the People's Councils, and advocated for specialist services for at-risk groups. Strug (2006) cites an interview with a Cuban social work educator who described how these practice developments drove educational reforms, including the creation of a 6-year social work degree program within the Department of Sociology at the University of Havana in 1998:

> We had to change our way of training social workers. We needed an educational program that would teach them how to work with Committees for the Defense of the Revolution and the Federation of Cuban Women [mass organizations], delegates [local elected officials], school teachers, and out-of-school-kids. (Strug, 2006: p. 755)

This was followed by the creation of paraprofessional social work schools to train out-of-school and unemployed youth, who had grown up during the special period, to work in Cuba's poorest neighborhoods, according to one social work student to become 'friends of the family, knocking on doors not touched by the Revolution,' as part of a 'Battle of Ideas' that aimed to strengthen Cuba 'economically, socially, and ideologically' (Strug, 2006: p. 757). Strug (2006) places Cuban social work in the context of socialism, reflecting

> the fact that the central government in Cuba has for half a century promoted collective goals and community ties, and has involved local self-government in the management of neighborhood affairs. (Strug, 2006: p. 758)

Bertera (2003) describes Cuban work with older people that combines health, social work, and geriatric professionals, integrated within the community and sustained by 'broad community participation,' not as an act of charity but as 'organized community action' in concert with the state. Voluntary work is widespread and is seen as a social duty, 'one of the ideological pillars of society,' and a resource on which social workers draw in their work (Bertera, 2003: p. 319). This demonstrates a role for social workers as organizers of people to meet one another's needs as part of a socialist process together with the state, contrasting with social work under capitalism to resist class attacks on working-class people by the state or to mitigate their most damaging effects.

Conclusion

Marxism emphasizes that realizing subjective agency, for practitioners and services users, requires analysis of the constraints imposed by objective conditions. Under capitalism, social work can facilitate social change, through political education, building alliances between oppressed groups, and helping people to cope with the alienation and exploitation caused by capitalism while they struggle to change oppressive structures. Under socialism, a radical shift in approach is needed for social work to retain its relevance, as RSW's goals of organizing society to meet human needs are no longer marginal or oppositional, but are pursued by a socialist state and political and mass organizations tailored to that purpose. At the same time, professional autonomy threatens to compete with the political leadership of the revolution. Approaches to social work and welfare in countries where Marxist-led revolutions have attempted to build socialism offer a rich source of experience, but are underdocumented in English. Recent steps toward broadening what constitutes social work, through the concept of 'popular social work,' represent a step forward in comparing social work approaches under such radically different contexts as capitalist states, states that are breaking down or fundamentally contested, and socialist states.

Marxist Archaeology

Antonio Gilman, Encino, CA, USA

Abstract

This article reviews the principal currents of explicitly Marxist thought that have arisen in archaeological investigations: the application of Engels's evolutionary stages in Soviet archaeology, the contributions of Gordon Childe, the critique of the ecological functionalism and scientism of the Anglo-American New Archaeology, and the social archaeology developed Latin America, Italy, and Spain.

Marxist archaeology is taken here to be the use of the principles of historical materialism as developed by Marx and Engels to analyze the dynamics of the past societies whose material remains archaeologists study. Such a definition must take into account, of course, Marxism's political importance, which has made its use as a guiding historical theory range from mandatory to proscribed, with various degrees of toleration in between. Archaeology is an expensive and cumbersome activity that requires extensive funding and official permits, so that political controls are relatively easily imposed, with a corresponding effect on how archaeologists present themselves. Completely uncensored, archaeologists may decide (in the interests not of prudence, but of persuasiveness) to omit explicit references to Marx and Engels with respect to matters on which Marx and Engels had nothing direct to say (i.e., almost all archaeological cases). Indeed, enough of Marxist thought has become assimilated into the mainstream of the social sciences that many archaeologists may be unaware of the derivation of their ideas. Marxist archaeology is, therefore, what archaeologists who say they are using Marxist principles do.

Soviet Marxist Archaeology

The first broad application of a Marxist approach to archaeology occurred in the Soviet Union. This took the form of applying the ethnological stages of Savagery, Barbarism, and Civilization that Engels (1972[1884]) had adapted from Lewis Henry Morgan's *Ancient Society* (1964[1877]) to the archaeological evidence from the Soviet territories. During the 1920s, most archaeologists carried on with traditional descriptive studies much as before, on the assumption that "because they were studying the history of material culture, their work accorded sufficiently with the materialist perspective of the new social and political order" (Trigger, 1989). During the 'Third Period' of collectivization and forced industrialization, however, orthodoxy along the lines indicated by Engels and Morgan was imposed from the center: unenthusiastic scholars were dismissed (or worse), regional associations promoting the study, and preservation of local monuments and antiquities were disbanded for glorifying the past, and so on (Klejn, 2012).

The result of this imposition, however, was the first systematic, large-scale sociological reading of prehistoric evidence, one that did not fail to render interesting and useful interpretations and to stimulate innovative research. Reading Engels into the preliterate past of the Soviet Union required a broadly functionalist approach that integrated all aspects of the archaeological record. As Trigger (1989) points out, the concrete results achieved in the 1930s in many ways anticipated those of the Anglo-American New Archaeology of the 1960s (a neo-evolutionist processual movement also rooted in Morgan by way of Leslie White (1959)). At the same time, however, the high political stakes of Marxist theorizing, and the intensely hierarchical institutionalization of archaeology under Stalin impeded critical analysis of Engels's propositions in the light of the emerging evidence, a critique all the more necessary given the provisional character of Engels's work. On the basis of the new, up-to-date ethnology of Morgan, Engels had been willing to revise extensively the initial reflections on primitive society and the development of the state that he and Marx had developed in works such as the *Formen* (Marx, 1965[1857–58]) and the *Anti-Dühring* (Engels, 1934[1877]). In the Soviet Union, however, the unilineal stage theory formulated by N.I. Marr, the first director of the State Academy of History and Material Culture, was not formally abandoned until Stalin himself denounced it in 1950, 16 years after Marr's death. Soviet Marxist archaeology was the product of a relatively small group of Bolshevist enthusiasts, so the post-Stalin relaxation of political controls led, as might be expected, less to the development of a critical Marxist archaeology than to a concentration on practical work in which such theorizing as did take place concentrated largely on explaining the diversity of the Soviet Union's archaeological record. This focus on 'ethnogenesis' had a greater affinity to the nationalist archaeology of Gustav Kossina than to the theoretical work of Marx and Engels (Shnirelman, 1995; *see* Archaeology, Politics of; Ethnic Identity/Ethnicity and Archaeology).

Childe

Outside the Soviet Union, the first archaeologist to develop Marxist perspectives systematically was V. Gordon Childe (Trigger, 1980). As professor of prehistory at Edinburgh in the 1920s, Childe (1925, 1928, 1929) had developed a synthesis of Kossinna's paleoethnological concerns with Oskar Montelius's comparative chronological approach on a scale that encompassed both Europe and the Near East. Childe was a man of the Left (he had been active in the Labour Party of his native Australia) and he took keen professional and political interest in emergent Soviet archaeology. The Soviet experiment showed

him how he could fit the prehistory he had elucidated into a larger evolutionary whole. He would recast the transitions from Savagery to Barbarism and from Barbarism to Civilization as the Neolithic and Urban Revolutions, respectively (Childe, 1936, 1942), stressing the dynamic interplay of production and social organization. At the same time, he saw no reason to accept the unilinealism of the Soviet school. Instead, he anticipated late twentieth-century world-system approaches by seeing Europe as peripheral to and dependent on the Near East (Childe, 1958). Finally, he grounded his interpretations in an explicitly realist epistemology (Childe, 1956) in which knowledge is socially constructed, but long-lasting to the extent that it is practical. Precisely because he adjusted the details of his historical reconstructions to the best evidence of his day, many of Childe's specific contentions are dated, but his consistent view that historical changes are rooted in the social relations of production continues to inspire research (e.g., Wailes, 1996).

'Western' Marxist Archaeology

Childe's eminence (and British tolerance of what could be regarded as eccentricity) permitted him to be a solitary exponent of Marxist prehistory in the West during the first part of the Cold War. A broader avowal of Marxist approaches to prehistory would wait until a generation of archaeologists, trained during the university-based radicalism of the late 1960s and early 1970s, attained professional independence. In the United States and Great Britain this renewed, explicit interest in Marxism arose in the context of dissatisfaction with certain aspects of the by-then dominant New Archaeology. This form of neo-evolutionism shared with Marxism many of the same concerns with the prevailing historicist theory and practice and so was susceptible in turn to a Marxist critique. (For detailed treatment with references of the New Archaeology, *see* Evolutionary Approaches in Archaeology; History of Archaeology; Theory in Archaeology; Archaeology and Science Studies.) This critique addresses both of the principal strands of the New Archaeology.

First, the New Archaeology was committed to cultural ecology as an explanatory strategy. Cultures were seen as analytically isolable, functionally integrated, homeostatic regulatory mechanisms in which change occurs due to demographic or environmental pressures external to the cultural system itself. Where small-scale, egalitarian societies are concerned, cultural ecology is not incompatible with Marxism (e.g., Marx, 1965), although attention to the internal tensions (contradictions) of kinship-organized societies may improve upon an innocent systems functionalism (e.g., Gilman, 1984; Saitta, 1997). In societies that exhibit substantial inequalities, however, notions that their privileged elites act as higher-order regulators of complex adaptive systems are wide open to critique from a Marxist perspective. Inasmuch as complex societies are driven by internal competition, the winners of which set themselves above and exploit the mass of the population, they cannot be adequately understood as systems in which an adaptive equilibrium benefits all their members (e.g., Gilman, 1981; Zagarell, 1986; Brumfiel, 1992). Furthermore, complex societies rarely develop in isolation: their class inequalities emerge in the context of external trade and warfare, so that analogs of the world-system approach to capitalism (e.g., Frank, 1967) can be applied to ancient cases (e.g., Frankenstein and Rowlands, 1978; Kohl, 1989; Frank, 1993). Finally, against the New Archaeological view that a society's ideational system consists of the information regulating its adaptive response to the environment, archaeologists have appealed to a Marxist view of ideology as means by which competing classes and factions legitimate their interests so as to control and manipulate others (e.g., Patterson, 1986; De Marrais et al., 1996; Bernbeck and McGuire, 2011). These critiques have been so effective that they have been absorbed into the mainstream of Anglo-American archeological thought.

Second, the New Archaeology insisted upon emulating the methods of the natural sciences by adopting logical–positivist research strategies. This scientism presents inherent difficulties (Wylie, 2000) and is clearly incompatible with a Marxist view of ideology, according to which archaeology would be a body of knowledge developed by social actors in accordance with their interests. Archaeologists have used Marxist ideas to show how the theory and practice of the discipline has been influenced not (or not just) by value-free scientific objectives, but by the social and economic constraints of its setting (Patterson, 1995). Thus, the pressures of sponsorship (e.g., Gero and Root, 1995) would generate archaeological models (e.g., Keene, 1983) and popularizations (e.g., Leone, 1981) that reinforce the necessity of present-day capitalist social relations by showing that they existed in the past. The argument that archaeological claims about knowledge reflect the interests of those who advance those claims can, however, be only a short step away from a self-defeating relativism that sees Marxism as an approach to understanding history that can only be judged on its own terms (e.g., Saitta, 1983).

In addition to providing a critique of nonhistorical materialism, Marxist archaeologists have sought to use the material record to examine the operation of capitalism (e.g., Leone and Parker, 1999), with particular attention to how it can illustrate the lives of the oppressed: such as racial minorities (Orser, 2007), miners (McGuire, 2008), and mill workers (Mrozowski et al., 1996). Study of the recent history and more remote past of the indigenous populations that stood in the way of the modern world system has, of course, been the central object of the prehistoric archaeology of North America and Australia. With some exceptions (e.g., Muller, 1997; Trigger, 1985), these have been uninformed by Marxist perspectives. Inevitably perhaps, the concrete reconstructions of the past arrived at by archaeologists (overwhelmingly of European descent) often conflict with the accounts of their own history developed by members of present-day First Nations. Sympathy for the victims of capitalism is an essential part of Marxism, but when scholars on the left (e.g., McGuire, 1992, p. 243) urge archaeologists to validate indigenous accounts of the past, they veer into a relativism that is more akin to Romantic nationalism than to Marx's Enlightenment rationalism.

'Southern' Marxist Archaeology

In recent years, the most systematic construction of a Marxist archaeology has occurred within the 'social archaeology' current in Latin America (e.g., Lumbreras, 1974; Sanoja and

Vargas, 1978; Bate, 1998; cf Patterson, 1994). In these areas as in post–World War II Italy or post-Franco Spain, Marxism has the prestige of being associated with the opposition to a capitalism operating under authoritarian political auspices. It differs critically from the 'Western' Marxist archaeology in that it is not so much a critique of New Archaeological processualism as a substitute for it. In Latin America, the dominant archaeological paradigm is the traditional historicism that preceded the New Archaeology in the United States and Britain, an historicism oriented toward an ethnopopulist emphasis on the indigenous roots of the modern nations (Vargas, 1995) and/or toward the development of archaeological resources for education and tourism. Archaeologists politically committed to the Left in Latin America have (where their presence has been tolerated) used a Marxist framework to build a processual alternative to the predominant historicism, one that does not suffer from the limitations of the adaptationist, ahistorical processualism developed in the US. Classic Marxist concepts, such as 'mode of production' and 'social formation' are combined with novel constructs such as '*modo de vida*' (mode of life) to develop a systematized basis for archaeological research that has none of the postprocessual distaste for an evolutionist grand narrative. In the 1960s, the Italian archaeologists of the Dialoghi di Archeologia group developed similar approaches in a Gramscian vein (e.g., Bianchi Bandinelli, 1961). In Italy, as in Latin America, institutional constraints have prevented this theory from being put into widespread practice; however, in Spain the democratization of the late 1970s was associated with expanded employment and funding in archaeology. This process in turn has led to active implementation of a variety of historical materialist research strategies (e.g., Ruiz et al., 1986; Vicent, 1998; Nocete, 2001; Lull, 2007; Criado Boado, 2012).

Conclusions

The societies that most archaeologists are concerned with were not at the center of Marx's attention and almost no information about them was available in his and Engels's day. To create a Marxist archaeology one must instead critically and creatively deploy the central themes of Marxist thinking. Archaeology is a discipline that requires institutional support, and Marxism, as a critical approach to historical inquiry, is not easily or fruitfully institutionalized. At the same time, archaeological evaluation of critical Marxist variables, such as property relations ("it is always the relationship of the owners … to the direct producers … which reveals the innermost secret, the hidden basis of the entire social structure" [Marx, 1967[1894]), is not a straightforward task (Gilman, 1997). As a result, Marxist interpretations of the archaeological records are only beginning to be developed.

Marxist Geography

Richard Peet, Graduate School of Geography, Clark University, Worcester, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Marxist geography came into existence as part of the radicalization of the social sciences during the 1960s and 1970s. It sees crises in society's relations with space and nature emanating from the deep structure of capitalism. These crises threaten human existence. Marxist geographers believe in social transformation to a new kind of rational, democratic society.

Geographical issues, like globalization, environmental destruction, and geopolitical contention lie at the center of social concern. Many scholars in the social and behavioral sciences have assumed deeply critical stances with regard to the origin of crises in the structures of capitalist societies. Marxist geography is one of these critical analyses. Marxist geography agrees with conventional geography that the focus of geographical study should lie on the relations between society and the natural environment including, in the term 'environment,' the veneer of earth space, the place where society's multiple effects on nature are concentrated (*see* Geography: Overview; Nature–Society in Geography). Marxist geographers argue that capitalism, as an entire way of life, has inherently destructive effects on nature and space. Marxist geographers argue that crisis is more severe in regions where capitalism is most developed, organizationally, technically, culturally, and economically. For Marxist geographers, ending environmental crises means ending the basic cause of the problem, and this in turn entails transforming capitalist societies. This radical intention differentiates Marxist geography, analytically, and politically, from conventional social and environmental studies and analyses.

History of Marxist Geography

The radical movement in geography began as part of a culture of political opposition that coalesced in the mid- to late 1960s. The leading issues of the time involved problems like inequality, civil rights, racism, sexism, and the environment, all brought into greater contention by geopolitical issues like the Vietnam War. Articles dealing with socially relevant geographical topics began to appear in the discipline's mainstream journals. Until that time, geography had mainly engaged in a conservative intellectual discourse, whether in the form of regional description, or the quantitative analysis of spatial distributions of cities and industries. In 1969, *Antipode: A Radical Journal of Geography* was founded, specifically to publish the new kinds of critical work. Early issues of the journal dealt with urban and regional poverty, discrimination against women and minority groups, unequal spatial access to social services, advocacy planning, Third World development, and similar topics. For several years radical geography used conventional philosophies and analytical techniques for studying this new range of more socially engaged issues. Only gradually did socially relevant radical geography, armed with an eclectic critical politics, turn into a more disciplined Marxist geography, aimed at the achievement of democratic socialism (Peet, 1977).

The transformation of radical geography into Marxist geography was informed by a key text, *Social Justice and the City*, written by Harvey (1973). This series of essays records the author's movement from a liberal, critical position, focused on moral issues of urban social justice, to a revolutionary position, based in a philosophy of historical materialism. As scholars and activists began to read Marx, in part stimulated by Harvey's work, in part propelled by the prevailing culture of protest, and in part compelled by the deficiencies of conventional reasoning, geographical thought was transformed, in content and depth, moving from an obsession with the empirical, the descriptive, and the quantitative, to an equally committed obsession with the philosophical, the social theoretical, and the politically engaged. The last 30 years of the twentieth century saw radical and Marxist geography emerging from the backwaters of a remote, conservative discipline to assume a place of prominence in contemporary critical social science as a whole (Peet, 1998). With the onset of economic recession in 2007–08, Marxism and Marxist geography contributed compelling analyses of the structural origins of systemic crises, resuming a central position in the discipline.

Historical and Geographical Materialism

The philosophical position adopted by Marxist geographers, often termed geographical materialism, is derived from the Marxist philosophy of historical materialism. Karl Marx and Friedrich Engels were followers of the German idealist philosopher G.W.F. Hegel. In Hegelian philosophy, events in the real world were determined by the prior thoughts of a World Spirit in a separate spiritual realm – the material realm was some kind of manifestation, or condensation, of transcendent consciousness. Marx and Engels eventually turned this belief back on its material base: consciousness, they claimed, was the product of matter, rather than its origin. Marx retained from Hegel's idealism dialectical conceptions like development through contradiction. However, this development was rethought in terms of real, materialist dialectics, rather than the dialectics of thought, as with struggles between classes, or the contradictory relations between society and nature. In a dialectical, geographical materialism, the natural and social

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72032-0

worlds are not seen as entities remaining eternally the same, but as interacting processes capable of rapid, and indeed dramatic, change.

Geographical materialism follows historical materialism, beginning its account of history with the natural bases of life, or the environments inhabited by groups of people, and with the modification of nature through human action. As with other animals, the assimilation of natural materials ('metabolism') was "the everlasting nature-imposed condition of human existence … common to all forms of society in which human beings live" (Marx, 1976: p. 290). Marx argued that human survival had to be earned by applying labor to the natural world: people are primarily workers. Human consciousness and intentionality result from a life process dominated by labor, and are not gifts from a benevolent God to his earthly sons and daughters. Hence, experience in the production and reproduction of human existence is interpreted to yield ideas that construct consciousness. As consciousness develops, as with science and technology, the productive forces employed in the social construction of continued existence improve, in the sense of becoming more powerful (but also potentially more destructive). This liberates human life from the immediate constraints of nature. Yet 'liberation' occurs through a contradictory process of social exploitation and political domination. The modern world is headed for problems from its inception.

For Marx, the social relations entered into during the production of the material basis of life (i.e., the labor process) have an inherently contradictory aspect. In particular, Marx focuses on social relations between a ruling class that owns the means of production – the raw materials, machines, buildings, infrastructures, and technologies that physically produce goods and services – and a working class, deprived of independent means of livelihood, and forced to work for the capitalist class to earn wages. Class relations between owners and workers, or between capital and labor, are based in the extraction of surplus labor time, in a process Marx calls 'exploitation.' Societies are exploitative when owners extract uncompensated labor time from direct producers. Used in such an exploitative way, the money that hires labor to produce value becomes capital (hence capital is formed by a social labor process rather than resulting from private entrepreneurship), and social relations are necessarily contradictory, in the sense that one class lives off another. At the same time, competitive relations among capitalists compel the reinvestment of capital in more efficient means of production. Hence, exploitation and competition are the social relations compelling capitalism's tremendous economic growth. For Marx, the exploitation process was an arena of intense social struggle, with the owning, ruling class using a combination of economic, political, and ideological force to ensure their dominance, and the working class resisting through overt means like social organization and rebellion, and hidden means, like reluctant compliance.

In such a context of competition, exploitation, and struggle, Marxists theorize that social consciousness has to be diverted into ideological forms. Primarily, ideologies rationalize and legitimate exploitation, but they also support competition as efficient, and excuse environmental destruction as necessary for economic growth and continued employment. Some Marxists have extended the notion of ideology deep into culture, claiming that even common sense is a form of ideology (Gramsci, 1971; Althusser and Balibar, 1968). In Marxism, even the democratic state is controlled by the rich – for example through buying elections and lobbying in the contemporary capitalist state. The total ensemble of social relations, forces of production, ideological forms of consciousness, and political institutions that made up any social system was termed, by Marx, the 'mode of production.' For Marx, history takes the form of a succession of modes of production: gathering and hunting societies, organized by primitive communal relations; agricultural societies, organized through tribal social structures; state societies, organized by payments of tribute, taxes, and rents; and finally industrial societies organized by capitalist social relations of competition and exploitation (Marx, 1976).

Social Relations with Nature

Following this analysis, Marxist geographers, as dialectical, geographical materialists, see advanced societies, armed with powerful technologies, organized by competitive and exploitative social relations, having disastrously destructive effects on society, culture, and nature. For Marxist geographers, development is a contradictory movement: the production of social surplus began a process of emancipation from natural constraints; yet emancipation was accompanied by internal social differentiation marked by institutions of domination like the state, patriarchy, and the market. The precise resolution of the contradiction between emancipation and domination forms the specific kind of society. The bourgeois revolution, the formative social process of capitalism, introduced a class society in which economic growth occurs not for the sake of meeting needs (food, shelter, essential services), but for purposes of making profit and accumulating capital by the ruling elite. While all societies have socially mediated relations with nature, capitalism differs in its higher degree of complexity: under capitalism, natural relations are determined by blind forces of profit and competition, rather than deliberative, democratic, human intention. Under the abstract dictatorship of competition, capital must expand continuously, stalking the earth in search of raw materials, appending nature to the production process. This argument leads some Marxist geographers (like Smith, 1984) to the conclusion that nature is now 'socially produced' in the sense that no original relation with nature is left unaltered, and no living thing unaffected. Yet the production of nature universalizes contradiction as capitalism creates new barriers – scarcity of resources, nuclear technology, and pollution of the entire earth environment. This suggests, for Marxist geographers, the 'natural inevitability' of fundamental, social transformation, a new form of society spurred by the 'revenge of nature' (e.g., the greenhouse effect).

Mode of Production and Space

Marxist geography also looks at the relations between modes of production and space. In some of this work, especially in structural Marxist geography following the ideas of Althusser

(Althusser and Balibar, 1968), space is seen as a 'level' or 'instance' in a mode of production. Each aspect of social life is theorized as having a particular relation with environmental space, each mode of production creates distinct spatial arrangements, and successions of modes of production alter the landscape in any given space – so medieval churches lie within four-lane highways leading out to super-shopping centers. The themes of social practice, consciousness, and space were developed originally by the Marxist philosopher and sociologist, Lefebvre (1991). He proposed an analysis of the active production of space to bring the various kinds of space and the modalities of their genesis within a single theory. Lefebvre's thesis, simply put, was that social space is a social product: every society, each mode of production, produces its own space. Space consists of natural and social objects (locations) and their relations (networks and pathways). Yet while space contains things, it is often thought of the relations between them. For him, people are confronted by many, interpenetrated social spaces superimposed one on top of the other, what he calls a 'hypercomplexity,' with each fragment of space reflecting, yet hiding, many social relationships (see also Soja, 1989, 1996).

A coherent version of this idea was developed by the urban sociologist Castells (1977). For Castells, any social form, like space, can be understood in terms of the historical articulation of several modes of production. By mode of production, Castells means the particular combinations of economic, politico-institutional, and ideological systems present in a social formation, with the economy determining the mode of the production of space in the last instance. In terms of this theory one can 'read' the resulting space according to the economic, political, and ideological systems that formed it. An economic reading concentrates on the spatial expressions, or 'realizations,' of production (factories, offices, etc.), consumption (housing, sociocultural institutions), and exchange (means of circulating goods and ideas). The politico-juridical system structures institutional space according to processes of integration, repression, domination, and regulation emanating from the state apparatus. Under the ideological system, space is charged with cultural meaning, its built forms and spatial arrangements being articulated one with another into a symbolic landscape. For Castells (1977: p. 127), the social organization of space can be understood in terms of the determination of spatial forms by each of the elements of the three instances (economic, politico-juridical, ideological), by the structural combination of the three (with economy determining which instance is dominant in shaping a particular space), but also (empirically and historically) by the persistence of spatial forms created by earlier social structures, articulated with the new forms, in interaction with the natural environment.

The intention behind this kind of work was to create a Marxist 'structural science of space' – that is an organized explanation of the structural order of the forces and relations that impinge on space. The idea was not how economy is 'reflected' in space, but how economy arranges the political, cultural, and social organization of space or, in a more sophisticated statement, how an economy is made up from its various spatial instances. Yet this kind of scientific abstraction sometimes gave structural work on space a quality of unreality, as though the contents of space were laid down by driverless social paving machines passing over it. Also the return effects of space on society are minimal and mechanical in some structuralist approaches. Basically the approach lacked the active mediation of human agency, people as individuals, organized by social relations into families, classes, and institutions, and informed by different kinds of consciousness (Gregory and Urry, 1985).

Spatial Relations

Marxist theories see the relations between societies – often termed 'spatial relations' by Marxist geographers – in terms of exploitation, conquest, and domination. During the 1970s, a series of articles drew out the spatial implications of Marxist theory in a 'capital logic' school of spatial thought. This kind of Marxist geographic theory began with contradictions in the historical dynamic of capitalism and moved to manifestations of these contradictions in space. Spatial relations between environmentally embedded social formations are thought of as modifying, and even transforming, their internal social, economic, and political contents. Thus, the geography of capitalism is composed of unevenly and differently developing social formations. In such approaches, interregional social relations are often theorized as spatial components of a more general internal–external dialectic. For Harvey (1975), the Marxist theory of economic growth under capitalism puts capital accumulation at the center of a dynamic and inevitably expansionary mode of production. This dynamism encounters barriers (in labor, means of production, markets) which precipitate crises (chronic unemployment, realization crises, etc.) with the eventual result of a shift in the capital accumulation process to a higher plane (new social wants, new markets, etc.). Newly 'rational' locational patterns and improvements in transportation and communication are an inevitable, necessary part of capital accumulation. But there is a spatial aspect to contradiction: in overcoming spatial barriers and 'annihilating space with time,' spatial structures are created which ultimately act as barriers to further accumulation. This is particularly the case when capitalism comes to rely on immobile, fixed capital (i.e., means of production fixed in space) rather than more mobile variable capital (i.e., labor). Then capital has to negotiate a path between preserving the value of past investments in the built environment (the urban landscape, for example) and destroying these investments to make new room for accumulation (urban renewal). The virtue of Marx's location theory, dispersed though it may be in textual fragments, lies in the way space can be integrated into "fundamental insights into the production of value and the dynamics of accumulation" (Harvey, 1975: p. 13).

In terms of geographical theory this dynamic theory of contradictions contrasts with conventional (bourgeois) location theory employing an equilibrium analysis of optimal spatial configurations: as Harvey claimed (1975: p. 13):

> The Marxian theory … commences with the dynamics of accumulation and seeks to derive out of this analysis certain necessities with respect to geographical structures. The landscape which capitalism creates is also seen as the locus of contradiction and tension, rather

> than as an expression of harmonious equilibrium … The Marxian theory teaches us how to relate theoretically, accumulation and the transformation of spatial structures and ultimately … the reciprocal relationships between geography and history.

Thus, the internal and external dimensions of space are linked to each other and with capital accumulation. Revolutions in the productive forces, the increasing scale of production, and the concentration and centralization of capital are paralleled by urban agglomeration in a widening international capitalist space.

Smith (1984) argued that different conceptions of space were produced by different types of human activities; hence there was a history of theories of space forming part of the history of the human experience. The increasing scale of human intervention in nature, with advance of the forces of production, is seen as the historical-material basis of a theoretical bifurcation of absolute, natural, and physical space (the world of physical and natural phenomena) from relative and social space (the humanly constituted field of social events). For Smith, the development of the forces of production transforms absolute (natural) space into relative (social) space in a contradictory movement. Development emancipates society from the constraints of natural space, leading toward 'equalization,' but only by sinking capital into certain spaces, producing 'differentiation' and a relativized space. These contradictory movements determine the specific forms of capitalist space as synthetic outcome: "Space is neither leveled out of existence nor infinitely differentiated. Rather the pattern that results is one of 'uneven development'" (Smith, 1984: p. 90). Integrating the geographical notion of 'scales' (urban, national, global) as levels of specificity, with temporal notions of rhythms, cycles, and long waves, Smith proposes a 'seesaw' dynamic of uneven development: "capital attempts to see-saw from a developed to an underdeveloped area, then at a later point back to the first-area which is by now underdeveloped" (Smith, 1984: p. 149) – for example the return of some manufacturing to deindustrialized regions, or at the urban level, where mobile capital destroys, then gentrifies, inner city neighborhoods. For Smith, the real resolution between equalization and differentiation can be achieved only by global political cooperation among working-class people.

The culminating triumph in this series of creative exegeses came with Harvey's *The Limits to Capital* (1982), a reading of Marx's *Capital* organized around three versions of a general theory of capitalist crisis. The first version sees crises of overaccumulation – more capital produced than opportunities for using it – resolved through violent episodes of the destruction of value, times when capitalists turn on each other, yet workers end up paying the social costs (Harvey, 1982: pp. 190–203). The second version examines the expression of productive crises in money and finance, speculative booms and busts which require the intervention of the state: in an internationalized economy, crises take the form of interstate competition over shifting the effects of devaluation, with national policies to export the effects of crises, and imperialism, neocolonialism, and even war as potential 'solutions' (Harvey, 1982: pp. 324–329). The third and last version integrates geographically uneven development: devaluations of capital are systematized into the continuous restructuring of space through interregional competition. Harvey focuses on 'switching crises' in the movement of capital from one place to another and crises in the hierarchy of capitalist institutions, so that problems which originate in the chaos and confusion of local events build upward into global crises. For Harvey, the basic rhythm of crisis involves regional economies, or more broadly regional class alliances, periodically alleviating internal crises through transformations in external relations in a spatial 'fix' which again has imperialism as its integral component – hence, "an interpretation of interimperialist wars as constitutive moments in the dynamics of accumulation" (Harvey, 1982: p. 443). What better reason, he asks, could there be for declaring that capitalism's time has passed, and that there is a need for a saner mode of production?

What difference does theoretical elaboration make for understanding contemporary sociospatial issues? Take for example the emergence of an intensified process of globalization in the late twentieth and early twenty-first centuries. Conventional explanations of globalization stress the development of transportation and communication technologies as means of overcoming the frictions of space – hence a global, rather than a national, economy. And clearly this is part of the story. But an overemphasis on technology disguises an unequal process of the accumulation and extension of power. Power means control, by a person or an institution, over the minds, livelihoods, and beliefs of others. Power accumulates into systems. So the term 'geography of power' refers to the concentration of power in a few spaces that control a world of distant others. With globalization, new kinds of power system have arrived on the world scene. A few financial centers control the global economy, and crises caused by speculation on the part of the financial elite become world crises adversely affecting everyone. Power has increasingly been accumulated at the global level by governance institutions – the G7/G8, the European Union, the Bretton Woods Institutions, and the United Nations. These institutions control the economies and livelihoods of people all over the world through policy devices like structural adjustment, the 'conditionalities' accompanying loans or debt relief, annual inspections by teams of experts, and similar strategies. For Marxist geography, globalization is analyzed through types of power accumulation – economic, ideological, and political – and the flows of power over global space. Marxist geography also participates in popular resistances to concentrated power by social movements and organic intellectuals (Peet, 2007, 2011).

Politics of Space and Nature

Marxist geographers argue, in general, that the social inequalities endemic to capitalist societies result in spatial inequalities, regional and local differences within and between societies. The capitalist world is split between countries that have far more production and consumption than their peoples need, so that a range of problems appear, from overweight children to excessive pollution, and countries that have too little, with their own range of problems, such as starving children and extreme vulnerability to natural disasters like earthquakes and floods. Some Marxist theories of space, based in dependency and world systems theories (Frank, 1969; Wallerstein, 1974),

argue that overdevelopment in the First World is predicated on underdevelopment of the Third World. Uneven spatial development also brings entirely different degrees of economic pressure to bear on the natural world, so that environmental crises appear unevenly as they accumulate into global catastrophes. This interaction between Marxist geography's spatial and environmental dimensions provides the theoretical basis for a range of radical politics linking development with nature. Marxist spatial theorists advocate evening out the development process so that basic needs can be met everywhere. Marxist natural theorists advocate producing and consuming less, while doing this sustainably. Both require fundamental changes in social organization, especially in the ways societies relate over space, and the way nature is treated and necessarily altered during the social production of existence.

Social scientists in the Western tradition of Marxism favor rational and democratic ways of controlling society's environmental and spatial relations. The notion of state ownership of productive resources has always been far weaker in the Western tradition of Marxism than in the Soviet or Eastern tradition. Marxists believing in all-powerful states have long been countered by others believing just as strongly in workers' self-management, cooperative organizations, participatory democracy, and democratic planning. Marxists essentially believe in extending democracy from the political sphere into all aspects of social life, especially the productive and reproductive spheres – that is, democratic control over factories, offices, schools, and families. Marxists think that people directly responsible for their fundamental social and economic activities can reach collective decisions that are more rational and farsighted than those reached by political and economic elites distanced from direct contact with real social practices. In this way democratic socialism is seen by Marxist geographers as the final culmination of the Enlightenment project of rationality, equality, and liberation.

Masculinity and Social Work Practice

Bob Pease, Deakin University, Geelong, VIC, Australia

Abstract

Approaches to working with men will be shaped by how we understand masculinity and men's lives. This article explores the challenges and directions for profeminist practice with men in social work by locating an understanding of men's lives in the context of patriarchy and the divisions of class, race, sexuality, and other forms of social inequality. The article concludes by outlining the implications in practice, of a profeminist approach to men as gendered workers in social work, engaging men as individuals and in men's groups, and working for structural change at the community and societal levels.

Introduction

Masculinity and the place of men in social work has until recently been a neglected area in social work writing (Christie, 2001a; Featherstone et al., 2007; Pease and Camilleri, 2001; Pringle, 1995). There is extensive social work literature that presents men and masculinities in an implicit and untheorized way, with mainstream social work texts rarely addressing men as gendered clients.

Feminists in social work have drawn attention to the prevalence of sexist attitudes and practices in social welfare and, during the last 25 years, feminist social workers have developed interventions and policies aimed at overcoming sexism (e.g., Day and Langan, 1992; Dominelli, 2002; White, 2006). Feminist practice with women has thus made significant contribution to critical social work practice. While the feminist social work literature has not said much about working with men, they emphasized the need for feminist thinking to infuse work with men. Building upon these early discussions, Cavanagh and Cree (1996) published the first feminist book that systematically examined feminist practice with men.

It is not surprising that attention has been directed toward women's issues in combating sexism in the welfare and human services sector. The majority of both social workers and welfare clients are women. However, it is increasingly recognized that addressing sexism necessitates an understanding of men as well as women. All social workers will have contact with men. Furthermore, the majority of the concerns that women bring to social workers are connected to their relationships with men.

Since the 1990s, a small number of social work texts have been published to fill this gap in human services literature (Christie, 2001a; Featherstone et al., 2007; Pease and Camilleri, 2001; Pringle, 1995; Scourfield, 2003). These books address diverse issues related to men, masculinities, and social work. This short article endeavors to do justice to the complexities involved.

Men in a 'Women's Profession'

A continuing issue facing social work is the gender imbalance of the human services workforce. Evidence suggests that the proportion of women in social work in North America (Sakamoto et al., 2008), the United Kingdom (GSCC Report, 2010), and Australia (Healy and Lonne, 2010) is increasing.

The framing of social work as a caring profession and the association of caring with women is one of the barriers that deters some men from considering social work as a legitimate career option. There also seems to be some societal ambivalence about men as carers, especially if this caring involves physical and personal care (McLean, 2003).

While social work has been historically regarded as a 'women's profession' due to the female majority in its workforce, predominantly female clientele, and association with caring, many of the values associated with hegemonic masculinity such as emotional distance, rationality, and technical expertise also characterize social work (Pringle, 1995). Orme (2009) argues that social work practice is predominantly a rational-technical project that reflects dominant forms of masculinity.

Women's majority status in social work leads to social work being referred to as a female-dominated profession (Simpson, 2004). However, the larger numbers of women in social work do not necessarily translate into female leadership in the profession (Scourfield, 2003). Women in social work still work within the patriarchal structures of employing organizations and may at times serve patriarchal interests, even if they are actively challenging them.

McPhail (2004) challenges the representation of social work as a female-dominated profession because despite constituting the majority of members, women do not control the profession. Curriculum content is still dominated by male social work theorists; and quantitative and masculinist approaches to research still predominate, at least in the West. McPhail argues that framing social work as a female-dominated profession hides sexism and male prejudice within social work. In her view, it is more accurate to refer to social work as a "male-dominated female majority profession."

Men are overrepresented in both management and higher status jobs in the social services. Studies of social workers demonstrate that women are less likely than men to undertake managerial roles in human services and earn less money than men in comparable positions (Bent-Goodley and Sarnoff, 2008; Sakamoto et al., 2008).

These inequalities are reflected in various forms of horizontal and vertical occupational segregation in social work (Sakamoto et al., 2008). Notwithstanding the influence of

feminist ideas on social work, the social work profession retains patriarchal, gendered practices and these gendered practices can be understood as representing an unequal gender regime and provide the context in which social work with men needs to be located.

Masculinity and the Issues Facing Men in Social Work

Issues associated with masculinity underpin the problems that men present in human service organizations. The general consequences of traditional masculinity that have been identified include emotional inexpressiveness, poor health, distant fathering, family breakdown, stress associated with competitiveness and overwork, the overrepresentation of men in substance abuse, high risk behaviors, homelessness, suicide, and criminality (Lichtenberg, 1999).

Various writers have suggested that men will change when they consider these costs of masculinity for themselves. However, the focus on the problems facing men has placed too much emphasis on the costs for men associated with patriarchal relations and given insufficient attention to the costs of these male practices to women and children. In this regard, Cowburn and Pengelly (1999: p. 198) make the distinction between "men with problems" and "men as problems." The latter category includes rape and sexual assault, violence against women in the home, sexual harassment, and sexual misconduct as a group norm.

The privileging of men does not mean that men do not experience pain in their lives. Men can be privileged and miserable simultaneously. Kaufman (1993) argues that men's lives involve both power and pain and that much of men's pain arises from men's power and privilege to constitute what he calls "the contradictory experiences of men's power." Thus, the patriarchal dividend is not totally successful in advantaging men because men experience emotional and physical costs associated with their dominant position (Whitehead, 2002). Connell (1995) acknowledges that for men, there are disadvantages associated with gendered privilege. Connell (1995) posits that many of these costs are by-products of the advantages men gain from the patriarchal dividend.

When the costs of masculinity are documented in popular books about men, these are rarely framed as the consequences of men's advantages. Populist writers of books about men talk about a 'crisis in masculinity' as men find their traditional privileges and symbolic power being eroded (e.g., see Biddulph, 2008).

Several writers have expressed concern about the ways in which men's physical and mental health issues position men as the 'new disadvantaged' (e.g., Connell, 2000; Whitehead, 2002). Whitehead (2002) argues that "the male crisis discourse" distorts the connections between hegemonic masculinity and men's health. The idea of masculinity in crisis may itself be a strategy enacted by men to reinforce male power because it focuses on men's pain rather than their privilege. Connell (2000) points out that most of the costs associated with patriarchy for men are not necessarily experienced by the men who gain most of the benefits. Many of the current health policies and programs for men, for example, fail to recognize the social and economic context of men's lives and the impact of class and race divisions on their health (Pease, 2009b).

To develop a critical framework for practice with men, issues facing men have to be conceptualized. These are confusing and unsettling times for many men as they respond to changes in women's lives and women's demands for gender equality. To make sense of their confusion it is important to understand men's experiences within the context of the patriarchal structures in society and their relationship to class, race, and gender regimes. Men and women who work with men in social work should have an analysis of the social construction of masculinities and an understanding of how the forces that construct dominant masculinities embed men and women in relations of dominance and subordination that limit their potential to be in partnership with each other (Dominelli and McLeod, 1989).

To the extent that the social construction of masculinity is ignored, it blocks insight into the real trouble in men's lives. Furthermore, if men do not grasp gender as socially constructed, then feminist critiques of patriarchy, dominant masculinity, and abusive male behaviors will be felt by men at a deeply personal level.

Theorizing Men and Masculinities

Approaches to working with men will be shaped by understandings of masculinity and men's lives. Depending upon whether masculinity is framed primarily from a biological, psychological, or sociological perspective, it will impact the ways of understanding the issues facing men. It will influence whether the focus is more on men's pain or men's privilege (Featherstone et al., 2007). Work with men has also been differentiated in terms of whether it has been supportive of feminism and gender equality (e.g., Featherstone et al., 2007; Pease and Camilleri, 2001) or whether it is nonfeminist (or even antifeminist) and oriented toward reproducing traditional gender roles and inequalities (e.g., Glicken, 2005).

There is currently an enormous volume of literature on men and masculinities. Theoretical approaches have ranged from sociobiological, psychoanalytical, Jungian, and sex role approaches, through to materialist and discursive approaches. I do not provide an overview of the different theories, but focus specifically on theorizing men's gender privileges and situated dominance in relation to women.

In spite of the vast scholarship on men and masculinities published in the last 20 years and the developing awareness that challenges traditional thinking about male dominance, the 'common sense' approach to understanding men continues to invoke the language of biological differences. Claimed biological differences between men and women continue to legitimize male dominance and gender inequality.

Biological and essentialist perspectives on men and masculinities tend to legitimize male privilege. Stephen Goldberg's (1973) *The Inevitability of Patriarchy* is perhaps the best historical example of this argument. Goldberg argues that differences in concentrations of particular hormones give men an 'aggression advantage' over women. He believes this 'aggression advantage' means that men will inevitably

dominate women, as "the hormonal makes the social inevitable" (Goldberg, 1973: p. 49).

The central argument here is that if inequality is based upon some natural order, opposition is futile. In this view, there is no point in trying to equalize the genders because patriarchy is an inevitable product of biology. Nor is there any point in changing the basis of gender relations because it will only upset the natural order. Consequently, the feminist vision of a gender equal society is doomed to failure. This sociobiological analysis is 'alive and well' in much contemporary popular writing about men (Biddulph, 2008).

Psychological and sex role perspectives on men and masculinities posit that male behavior results from customary expectations that are internalized by men. In the 1970s, men were encouraged to "break…out of the straight-jacket of sex roles" (Farrell, 1975: p. 8). This theory was updated in the 1980s (Pleck, 1987); and from the 1990s it was reframed as gender role theory (Shimanoff, 2009) An implication of this approach is that men can transform themselves without reference to wider social processes, the male role being something men could dispose of, allowing the human being in the man to emerge.

One of the major limitations of sex-role theory (and the gender role theory that followed it) is that it underemphasizes the economic and political power that men exercise over women. Male and female roles are seen to be equal, thus enabling men and women to engage in a common cause against sex-role oppression. What is consistently missing in sex-role theory is the extent to which men's gender identities are based upon a struggle for social power. There is no evidence that liberating men from the traditional male sex-role will lead to men relinquishing their privilege and social power.

Sociological perspectives on men and masculinities emphasize that gender and masculinity are socially constructed throughout life. Following Connell (2000), it is most useful to understand men and masculinities as involving six key dimensions: (1) multiple masculinities that arise from different cultures, different historical periods, and different social divisions between men; (2) different positions reflected in these multiple masculinities in relation to power, with some forms of masculinity being hegemonic and dominant, while other masculinities are marginalized and subordinated; (3) institutionalized masculinities embedded in organizational structures and in the wider culture as well as being located within individual men; (4) embodied masculinities that are represented physically in how men engage with the world; (5) masculinities produced through the actions of individual men; and (6) fluid masculinities that change in relation to the reconstructive efforts of progressive men and in response to changes in the wider society. Within this theoretical context, Connell (1995) identifies four forms of masculinity: hegemonic, complicit, marginalized, and subordinate.

Hegemonic masculinity is the culturally dominant form of masculinity that is manifest in a range of different settings. Such masculinity is idealized and promoted as a desirable attainment for boys and young men to strive toward. It is presented as heterosexual, aggressive, authoritative, and courageous (Connell, 1995). The manliness of men and boys are judged by their ability to measure up to this normative notion. Sporting prowess, the role of men as providers, work status, and power over women are key signifiers of this form of masculinity. Hegemonic masculinity establishes the foundations for men's violence against women. Many writers have noted the close links between exalted masculinity and the legitimization of violence, especially in response to any form of threat (Messershmidt, 2000).

Although the majority of men do not adhere to hegemonic masculinity, it represents the most valued form of masculinity and all men are positioned in relation to it. It does not have to correspond to the lives of the majority of men to hold power over the male concept of being a man.

The majority of men engage in what Connell (1995) refers to as complicit masculinity. Complicit masculinities refer to those men who do not meet the normative standard of hegemonic masculinity but benefit from it in various ways. The concept of complicit masculinity is useful in understanding how men, who do not regard themselves as oppressors, reproduce male dominance and privilege.

Complicit masculinities also maintain the structures and ideologies that reproduce male violence. While the majority of men may not engage in excessive forms of hegemonic masculinity, they do not challenge patriarchy and male privilege that support this form of dominance, because they adhere to the dominant discourse and benefit from it.

Marginalized and subordinate masculinities are useful in understanding the relationship between gender and other dimensions of stratification, such as class, race, and sexuality. Connell (2000) uses these concepts to illustrate how diverse masculinities are marked by hierarchy and exclusion. The resultant hierarchy of masculinities means that men do not benefit equally from male privilege.

Diversifying Men and Masculinities

A new stage in which variations among men are seen as central to the understanding of men's lives has begun. It focuses not on masculinity as a singular term but explores masculinities. Men are as socially diverse as women and this diversity entails differences between men in relation to class, ethnicity, age, sexuality, bodily facility, religion, world views, parental/marital status, occupation, and propensity for violence.

Differences are also found across cultures and through historical time. The discourse about 'masculinity' is constructed out of 5% of the world's population of men, in one region of the world, at one moment in history. Ethnographic work in different cultures indicates how nonwestern masculinities can be very different from the western norm (Connell, 2000).

Anthropology has studied men's practices in nonwestern contexts. Some important studies are: Hertdt's (1981) study of the boy-inseminating rituals among the Sambia of Papua New Guinea; Silberschmidt's (1991) study of the changing gender roles in Kenya; Gutmann's (2003) edited papers on studies of masculinity in Latin America; and a study by Karim (1995) on gender relations in Asia, which considers the changing subjectivities and practices of men.

Cornwall and Lindesfarne (1994) emphasize the need to add the critical study of men's practices to attempts to

understand gender regimes in various parts of the world. Hofstede et al. (1998) examine different countries through how they mirror dimensions of masculinity and femininity, and construct a typology that measures the differences between what they call feminine and masculine societies. Gilmore (1990) provides one of the early comprehensive pieces of research on how men in different cultures perceive and experience manhood.

As a heterogeneous group, men do not benefit equally from gender domination. Issues of race, sexuality, class, disability, and age and the interaction between them complicate men's gender dominance in social work. Intersectional analyses can reveal experiences of both privilege and subordination. Multiple forms of social difference shape both unities and differences among men. These analyses provide a framework for designing interventions with men, which take into account their different placements in relation to privilege and oppression (Pease, 2009a).

Developing a Profeminist Sensibility among Men in Social Work

Men *can* change in the direction of feminism. They have choices as to whether they accept patriarchy or work collectively against it. Before men can organize collectively, they must transform their subjectivities and practices.

Although men cannot escape their material position in patriarchy, men can change their ideological and discursive position by drawing upon feminist standpoint theory (Harding, 2004). The advantage of standpoint theory is that it relates to both structural location and the discursive construction of subjectivity, to distinguish between a 'traditional man's standpoint' and a 'profeminist man's standpoint.'

A traditional man's standpoint is based on the privileges and powers that men have and it excludes the perspective of women. A profeminist man's standpoint involves an ability to be critical of man's traditional position in society and its contribution to the inequality of women and the development of an ethical and moral commitment to address inequality and discrimination because it causes harm (May, 1998).

Men can change their subjectivities and practices to constitute a profeminist man's standpoint. The process of change is itself a requirement in formulating a profeminist man's standpoint. Men have to change their vantage point if they want to see the world from a different position and this entails more than just a theoretical shift. It requires men actively to engage in profeminist struggles in both the private and public arenas.

Profeminism involves a sense of responsibility for a man's own sexism as well as other men's sexism, and a commitment to work with women to end men's violence (Pease, 2009a). It acknowledges that men benefit from the oppression of women, drawing men's attention to the privileges men receive as men and the harmful effects these privileges have on women. Profeminist men also recognize that sexism has an impact on men as well as women. Systemic male dominance dehumanizes men too, as evidenced in stress-related illnesses and emotional inexpressiveness.

Over 25 years ago, Tolman et al. (1986: pp. 66–73) articulated 11 principles for a profeminist commitment among men in social work: develop a historical, contextual understanding of women's experience; be responsible for themselves and other men; redefine masculinity; accept women's scrutiny without holding them responsible; support the efforts of women without interfering; struggle against racism and class consciousness; overcome homophobia and heterosexism; work against violence in all its forms; do not set up a false dichotomy between ones self and other men; act at individual, interpersonal, and organizational levels; and attend to process and product. They noted that very few men had been proactive in promoting feminist values such as these in social work and that men had contributed very little to ending sexism (Tolman et al., 1986). Written in 2013, this article reveals that little has changed. Nevertheless, men in social work have an important part to play in challenging sexism.

Encouraging the development of profeminist practice by men in social work is a natural expression of antioppressive practice with regard to gender. While antioppressive practice generally, with its focus on challenging oppression, is an appropriate framework within which to examine antisexist and profeminist practice by men (Cavanagh and Cree, 1996), Pease (2006) argues that antioppressive practice has been slow to encourage practitioners who are members of dominant groups to examine their own privileged positions.

To what extent then do men in social work recognize their gender privilege and to what extent are they willing to give up the privileges and power of their position? If men are to play an antioppressive role in relation to gender in social work, they will need to embrace a commitment to profeminist practice. In the context of wider antioppressive theory and practice, social work education needs to develop specific knowledge and skills to inform a profeminist commitment by men in social work. If men gain unearned benefits from their presence in social work, they have a responsibility to challenge the basis of those entitlements (Pringle, 1995).

Working with Men in Social Work

Pringle (1995) identifies four levels at which male social workers should engage in antioppressive practice: one's own behavior, individual work, group work, and structural change at the community and societal levels. This remains an useful framework to unravel the various dimensions of social work practice with men.

Working on One's Own Social Location

The starting point for profeminist practice for men, involves critical reflection upon the privileges associated with his individual position in the gender order and the gendered division of labor within social work. Christie (2001a) has stressed the importance of men as social workers, critically reflecting upon and challenging their gendered privilege and the gendered nature of their work. Pringle (2001: p. 45) similarly argues that male social workers "have a particular responsibility to engage in challenging those oppressive

structures of power from which they may benefit directly." This requires men in social work to monitor and challenge their own behavior and recognize the contradictions and dilemmas arising from their position.

Individual Work with Men

Men often want to change but they do not want to relinquish their power. A profeminist approach encourages men to rethink their power. It involves what Cree (2001: p. 161) calls 'critical engagement' – how to "build open connection with men while at the same time not being seen to condone their behaviour or attitudes."

Many of the beliefs men hold are the causes of the troubles in their lives. Thus, the starting point for work with men is to assess their beliefs (Russell, 1995). What beliefs does the man hold about masculinity? What are the sources of these beliefs? What are the potential harmful effects of these beliefs? How are these beliefs associated with the difficulties that the man is experiencing?

Male socialization leads to individual beliefs that can promote abusive behaviors (Russell, 1995). Men need to be helped by male social workers to acknowledge their tendencies to act oppressively and they should be assisted to devize strategies for avoiding those situations and changing their behavior. While men changing themselves will not in itself address the structural components of gender oppression, they should nevertheless be encouraged to develop wider repertoires of behavior and models of masculinity that are not associated with violence, control, and objectification (Pringle, 1995).

Group Work with Men

Antipatriarchal consciousness-raising group work with men can clarify the social dimensions and historical shifts in masculinities. Such consciousness-raising in men's groups can provide a link between personal experiences and the wider social context of men's lives. Men can come to understand their own sexist behavior and develop emotional support from other men to encourage their antisexism.

Profeminist group work emphasizes the importance of working in groups with men who oppress and disempower others, where male prejudices and oppressive behaviors can be challenged (Pringle, 1995). As Hearn (2001) comments, profeminist group work models educate men about the oppressiveness of their beliefs and behaviors and involve them in analyzing their use of power and control tactics, to enable them to move toward more equal relationships with women, within the limitations imposed by the structurally unequal gender relations within patriarchy.

Creating Change at Community and Societal Levels

Feminist and profeminist writers in social work emphasize that personal change does not go far enough and they advocate the importance of connecting personal change with cultural and structural changes (Cree, 2001). Work with men should be one aspect of a broader strategy for changing unequal power relations between women and men.

For example, men need to become more actively involved as partners with women in social movements against violence toward women (Pease, 2008). However, as the involvement of men in the prevention of male violence has become more widely supported, I have become concerned that the tensions, dilemmas and dangers of such involvement have not been adequately addressed. These dangers include: reducing funding for women's services and programs, weakening their feminist orientation, silencing women, taking over their campaign, colluding with violent men, gaining more praise, and failing to earn women's trust (Pease, 2008).

When developing alliances between women and men, particular conditions have to be met and specific principles adopted, to address the potential problems associated with such partnerships (Pease, 2008). The theoretical premises underpinning men's involvement in the prevention of violence has to be based upon feminist theory and critical scholarship on men and masculinities. This might ensure that involving men in the prevention of male violence does not replicate the same structures and processes that reproduce the violence being challenged.

Conclusion

Not examining the social construction of masculinities in social work leads to failure in acknowledging how masculinities impact women's lives. To the extent that issues of men and masculinity are discussed in social work education, the focus tends to be on the costs of sexism for men and how such costs may encourage men to be more responsive to feminism.

It is important that social work with men locates men's lives within an understanding of patriarchal gender relations and that such work is committed to transforming those gender relations. While the gendered belief systems of men are only a part of the processes that perpetuate gendered inequality, they are amenable to intervention at the individual and collective level. Challenging the abusive beliefs of men makes an important contribution to respectful and egalitarian practices (Featherstone et al., 2007).

If more men are to be recruited into social work, the debate about the gendered nature of caring work has to be reignited within the profession and in social work education. The social work professionals and social work educators need to interrogate the gendered assumptions about nurturing, caring, intimacy, and love which are embedded within social work. Ascribing caring to women and femininity reproduces patriarchal discourses by devaluing women's practices in social work and legitimizing men's avoidance of caring (Camilleri and Jones, 2001). The challenge for the profession is to encourage men and women in social work to understand how affective inequalities in the delivery and the acceptance of care and love, reproduce inequalities in economic, political, and social relations (Lynch et al., 2009). Thus, fostering caring and nurturing masculinities is an essential part of promoting gender equality in the profession and wider society.

There are progressive and important roles for men in social work in promoting a more egalitarian profession. These require clarity about what constitutes 'good practice' for men and awareness of the dangers and problems, as well as the

possibilities, associated with increasing male presence in social work.

Some men in social work do not subscribe to dominant forms of masculinity. Social work as a profession needs more men who are critical of hegemonic masculinity and who are aware of the gendered injustices associated with male privilege and unearned male entitlements. I have argued that if men in social work are not actively promoting profeminist practices, they will reproduce an unequal gender regime within the profession.

Abstract

This article explores contemporary scripts of masculinity. Scripting theory allows for behaviors to be examined in regard to individual actors, interactions between individuals, and also how these are influenced by culture more broadly. Each of these levels of scripting is discussed independently as it relates to the construction of masculine scripts. Although these scripts guide individuals in their social interactions, it is necessary to understand how multiple scripts emerge. Here, the ways in which masculine scripts are constrained by social structures to produce particular masculinities are examined in regard to age, sexual orientation, class, and race.

Scripting Theory

Scripting theory was developed by Gagnon and Simon in the late 1960s and early 1970s. This theory has had an incomparable impact on the field of gender and sexuality studies within sociology. Simon and Gagnon looked for explanations of human sexual behavior that went beyond the biological. They write, "Unlike most sociologists of a generation earlier than us, our preference was to yield as little as possible to the explanatory power of biology in any of its guises" (2003: p. 492). As students of the Chicago School, they were well versed in the notion of the self, and applied this train of thought to gender. In so doing, they foreshadowed the movement toward social constructionism that was to come, first applying aspects of social learning to gender. The shift from social learning to social construction implied more agency on the part of the actor, as well as a recognition or rejection of social norms and cultural narratives around behavior. Simon and Gagnon saw the enactment of gender as central to one's identity, and were able to see the linkages between private acts and public expectations, positing that gender was learned through interaction with others, and also within the large-scale cultural narratives that proscribe ways to behave.

The underlying ideology of sexual scripts, the idea that meanings are generated through social interaction, paved the way for a variety of work, not only in sexuality studies within sociology, but in gender studies across disciplines. The most significant of these subsequent trends is the idea of gender as a performance. As Kimmel writes

> This effort to understand both the multiple meanings of sex and sex's centrality in the construction of identity set Gagnon and Simon's work apart as revolutionary; indeed, their breakthrough book *Sexual Conduct* (1973) heralded the new paradigm from which all subsequent readings of sexuality in the social sciences and humanities have sprung. Without Gagnon and Simon, there could not have been a Judith Butler. (Kimmel, 2007: p. ix)

Levels of Scripting Theory

Simon and Gagnon recognized that cultural context tells individuals ('actors') what is appropriate to do, when, and with whom. They also recognized that interpersonal interaction shapes behavior, so that when one person violates a social norm or expectation, they are not likely to repeat the act in the same way. They did also honor the personal choices and fantasies of the actor (the intrapsychic); however, they see these as rooted in social norms and expectations instead of individual biology. These three interrelated levels of scripts allow for gender and sexuality to be fluid and change over time and across cultural contexts. One of the major contributions of their work is that they accounted for differences in gender, foreshadowing the move of modern gender theory, feminist theory, and queer theory toward social constructionism.

The cultural element of scripts describes the large-scale messages that exist in different societies about gender. There is a set of cultural messages that proscribe behavior in a general context, as well as sets of messages that are more specific to different contexts, subcultures, and historical time periods. These messages are ubiquitous, but because specific messages may contradict one another, their utility as general guidelines for behavior can be problematic.

Many of the cultural messages about gender and appropriately gendered behaviors are simultaneously messages about (hetero)sexuality, as the enactment of (hetero)sexuality is an important element of the masculine script. These cultural narratives set up gender as if their categories were mutually exclusive, so that any behavior, body, or actor that is not explicitly masculine must be somehow feminized, and behavior that is not adequately feminine is denigrated as masculine, or just inappropriate.

One of the enduring cultural messages, albeit rooted in biology, indicates that men are geared to seek out multiple sexual partners, while women are supposed to guard their fertility and therefore be more selective about when and with whom they procreate. As these messages endure throughout decades, they translate into the often-repeated ideology, which dictates that males should seek sex and women should seek love (McGinty et al., 2007). This translates into a large-scale acceptance of male pleasure-seeking behavior, as well as providing a rationale that neutralizes such behavior: it is often excused as 'boys being boys.' Moreover, the ubiquity of such messages reinforces the masculine script as an enactment of heterosexuality.

The interpersonal element of gender scripts is also significant in that the communication among peers is used to deploy new

meanings or evaluations of behaviors. The opinions of the peer group are instrumental in shaping the way an actor behaves, as well as how one evaluates the behavior of others. It is within the interpersonal context that a label, such as 'fag,' is potentially devastating for young boys (Pascoe, 2007), as it is a public statement about an unsuccessful performance of masculinity. If a young male sees a peer labeled as 'fag,' he is less likely to engage in a similar behavior. In this way, the peer group is a significant regulator of behavior (Roseneil, 2005) and simultaneously becomes a site where one can earn or lose status (Kimmel, 2008; Kalish and Kimmel, 2011; Armstrong et al., 2009, 2012; Arnold, 2010; McGinty et al., 2007; Paul, 2006).

The third element of sexual script theory, the intrapsychic, is the least-theorized (Plummer, 2005, 2007) aspect of scripting. Relating to the individual fantasies, thoughts, and sensations that affect gender and sexuality, the intrapsychic level is significant because it allows for the introduction of pleasure. Pleasure, or corporeal sensation, is an important element of sexuality, and it affects how choices are inscripted on the body (Powell, 2008). Powell (2008) sees this as an embodied gender practice: "In using this term, I refer to the ways in which gendered norms and discourse are enacted through the body in everyday practice; in thoughts, feelings, desires, and responses, in a way that is not always subject to individual recognition and change" (p. 170). Following the work of Pierre Bourdieu, Powell (2008) posits that this embodied gender practice is the product of the culmination of social construction and social structure inscribed on the bodies of actors, a sexual habitus, if you will. While recognizing the intrapsychic as another site in which gendered messages influence conduct, scholars (Powell, 2008; McNay, 2000) also see the possibility for the creation, or renegotiation of new gendered selves.

As a theory, sexual scripts have remained fluid, and have been extended to explain sexual behavior in a variety of contexts. Indeed, the benefit of the three interrelated levels of sexual scripts (cultural, interpersonal, and intrapsychic) allows for different scripts to emerge in different historical and cultural contexts.

Critiques

While the theory of sexual scripts has remained viable over the decades since *Sexual Conduct* came out, it has been challenged. Perhaps the biggest challenge to sexual scripts is that it does not account for the corporeal. The intrapsychic level of scripting allows for behavior to be generated from fantasy, but the script theory does not explicitly or implicitly discuss the meanings of feelings, activities, and sensations of the body. As the sociology of the body has developed, this criticism has gained momentum. Plummer (2005) is not suggesting that script theory itself does not allow for involvement of the bodily reactions to sex, rather that much work in sexuality has taken the actual bodies that perform sex for granted. The corporeal body is important in guiding decision making, even if the actors themselves are not able to situate those corporeal feelings into the larger social and cultural context promoting sexuality, or to a lesser extent, to be able to interpret those feelings as being mediated by their peers and the culture in which they live.

Another challenge to scripting theory, acknowledged by Simon and Gagnon themselves, is that while the three levels of sexual scripts are interrelated, and one level may offer a context through which the others may be viewed, the three levels (cultural, interpersonal, and intrapsychic) do not offer 'the power to provide a comprehensive understanding of the other' (Simon and Gagnon, 2003: p. 493). Again, more recent work on specific cultural settings such as fraternities or colleges offers some insight into how structural forces affect behavior, but more work could be done to explain how these forces impact the interpersonal and intrapsychic implications for the actors.

A third challenge to sexual scripts is a more postmodern reading, calling for attention to structural inequalities and their impact on sexual scripts (Jackson, 2007), which we have attempted to address above. According to Stevi Jackson:

> The locations we find ourselves in are shaped by material social circumstances and our location within gendered, classed, racialized, and sexual hierarchies; our definitions of those situations and, in particular, whether our definition "works" for us depends on our social and cultural resources. If we take seriously the idea that our sexual lives are simply one facet of our broader social lives, then we must recognize that our sexual selves are shaped within profoundly unequal local, national, and global social orders. (Jackson, 2007: p. 13).

Hence, structural inequalities cannot be ignored when looking at how social forces affect individual behaviors. In an increasingly global world, where large-scale inequalities persist even as information flows rapidly, factors affecting the sexual script for one actor will change for another actor with access to more resources, information, technology, social recognition, and support.

Specific Contexts and Scripts of Masculinities

Masculinities across the Life Course

Due to their recursive relationship with cultural narratives about appropriate behaviors, scripts of masculinity change over the life course. As a male ages, his enactment and understanding of the masculine script will be reinforced by various sources of socialization: at early ages, the family is an important regulator of gendered behavior; through adolescence and emerging adulthood, the peer group becomes more important, and throughout adulthood and middle age, both distal and proximal sources can reinforce behavior.

Regulation of gender enactment starts early, sometimes before birth, as parents will project notions of gender to the behaviors of an infant, characterizing the instinctual grasp of a finger as strength. Parents regulate the enactment of gender in their children by rewarding appropriately gendered behavior and by punishing or correcting other behavior. Young boys learn the script of masculinity early on, encouraged to engage in rough play and physical activity, while being steered away from expressive toys. Most importantly, boys are taught that they are not girls, and they learn that to be associated with anything feminine is bad, for example, as they are instructed not to cry or show emotion. In childhood, the masculine script emphasizes difference from the feminine.

Schools cement gendered scripts by segregating boys from girls in gym classes, and by guiding boys into different, more physical, activities from their female peers, reiterating the emphasis on difference, and separation from anything feminine. During adolescence, peers become a significant reinforcement of the masculine script. It is during adolescence that the masculine script begins to emphasize the enactment of heterosexuality. In adolescence, the distance between boys and girls grows, and within the male peer group, heterosexual performance is emphasized (Pascoe, 2007). Also during this time, the enactment of successful masculinity becomes more public, and aggression, dominance, and violence are valued, as is the denigration of anything feminine.

In emerging adulthood, the masculine script underscores the performance of heterosexuality, and begins to stress dominance over anything feminine; so successful male performances will not only show a difference from females, but also display dominance over females sexually, as male sexual aggression is normalized and condoned. Also during this time, views about appropriate behavior emerge, highlighting the double standard regarding sexuality, where males will be rewarded for having multiple sex partners (i.e., positively termed 'a player'), while females will be scorned for similar behavior (i.e., with the label of 'slut') (Hamilton and Armstrong, 2009).

Emergent adulthood is an important liminal stage, where males are affected by the combination of scripts geared toward adolescent males, as well as those geared toward older men. In this time period, we see some elements of the adult masculine script emerge, such as the emphasis on responsibility and the status enhancing the effect of conspicuous consumption. Due to this, some young men may feel a sense of pressure in terms of keeping up with their peers in regard to both sexual accomplishment with women as well as with an accumulation of material goods that display wealth and status.

Because the cultural narratives, which shape gendered scripts, are themselves changing across time, culture, social class, and geographic region, we can see different scripts for different types of masculinities. However, many elements of hegemonic masculinity endure over time. In the words of Erving Goffman (1963, cited in Kimmel, 2000: p. 11), the successful performance of masculinity involves a man who is: "a young, married, white, urban, northern, heterosexual, Protestant, father, of college education, fully employed, of good complexion, weight, and height, and a recent record in sports". The emphasis on bodily strength, athleticism, and gainful employment are all central to the successful enactment of masculinity, even in more specific scripts of masculinity 50 years after this quote was originally written.

Masculine Sexual Scripts

The heterosexual masculine script is quite similar to the hegemonic masculine script, prizing conquest of women and an insatiable libido. Within this script, males are rewarded for sexual prowess, and they are able to earn status with their peers for being able to 'get' highly prized sexual partners. The ability to engage in sex acts without emotion is also emphasized in the masculine script, as emotion itself is typically associated with femininity. This script is largely devoid of meaningful interpersonal relations, as hegemonic heterosexual masculinity rewards sexual activity, and sexual behavior becomes a means for establishing status with male peers more than a means by which to establish a meaningful connection with female partners (Kalish and Kimmel, 2011; Kimmel, 2008).

Despite the fact that the appropriate intimate sexual relationships for men are with women, their appropriate social relationships are with other men. This social distance from women reinforces the idea that women are culturally and socially inferior to men. Thus, men's social lives are focused largely around their relationships with other men through sports, social clubs, fraternities, and other all-male institutions (Flood, 2008; Kimmel, 1996). These homosocial relationships put men at constant risk for that intimacy to be seen as sexual rather than as purely social. In order to maintain their masculine identity, men must socialize with other men, but do so in a manner that puts them above suspicion of homosexuality by relying on regular displays of homophobia to ensure that their masculinity is maintained (Kimmel, 1996).

The script for homosexual masculinity both draws from and simultaneously serves as a challenge to hegemonic masculinity. Although homosexuality is frequently tied to femininity, homosexual masculine scripts often reject femininity, asserting their masculinity despite their sexual orientation. Similar to the script for heterosexual masculinity, the script for gay men emphasizes their sexual prowess. Additionally, the script for homosexual masculinity stresses the importance of physical appearance, especially that of one's partner (Klinkenberg and Rose, 1994). Like their heterosexual peers (Kimmel, 2008; Kalish and Kimmel, 2011), gay men gain status by having an attractive partner. Also in accordance with the masculine script for heterosexual men, sex is prioritized over emotion. However, the script for gay men allows for more emotionality than heterosexual men, as well as some encouragement of more expressive emotions. Particularly, increased concern regarding safer sex practices is stressed more in the script for gay men than their heterosexual peers (Klinkenberg and Rose, 1994).

Class-Based Masculinities

Class plays an important role in the ways in which particular men enact masculine scripts. While all men may aspire to the hegemonic ideal of masculinity, not all men can realize that ideal in the same ways. As wealth is directly implicated in realizing that ideal, men, particularly in the lower or working class must often rework their enactments of the masculine script in ways that reinforce their own masculinity as another legitimate display of masculinity. As such, men are structurally constrained in their choice, an enactment of masculine scripts.

One of the dominant features of masculinity, particularly for white males, has been the role of provider and breadwinner, and one of the primary challenges to white working-class masculinity involves the threat to that role that has occurred with the increasing numbers of women and minorities entering the workforce (Kimmel, 1996; Morgan, 2005). These changes directly affect men's ability to serve as the provider in their families in several ways. First, the entrance of both women and minorities has led to a decline in wages, frustrating men's ability to be the sole provider in the family. Secondly, increased competition for jobs creates hostility between men for scarce jobs. In this process, working-class

men, especially white working-class men, often turn to blaming other minorities for their inabilities to find work or to find work that will support their families. They see themselves as hard-working men who are being deprived of the opportunity to support their families. Even those who are employed often feel frustrated with low-wage jobs that provide them with little authority, autonomy, or social status (Morgan, 2005; Weis, 2006).

The frustration of lack of autonomy in the workplace can carry over to the home, where men feel that they are able to exercise their control (Morgan, 2005). Even though working-class men may be dissatisfied with their ability to fulfill the demands of the provider role, they are still the heads of their families. This allows working-class men assert their dominance in the home, reinforcing the separation between the masculine and the feminine. Even in situations where the woman in the home works, her work is generally seen as secondary to his work and his role as provider (Morgan, 2005).

In addition to reifying the differences between themselves and women in the home, working-class men may also draw on sexism and homophobia to effeminize other men. Working-class jobs often involve hard, physical labor, and working-class men claim this as a superior form of masculinity to middle- and upper-class men, whose jobs require little physical labor, leaving their bodies softer and more effeminate. Men's distancing themselves from middle- and upper-class men in this way reframes aspects of masculinity to conform to a working-class script (Kimmel, 1996; Morgan, 2005; Pyke, 1996).

Racialized Masculinities

Just as there are structural constraints to masculine scripts based on class, race/ethnicity is another social context, which constrains and produces alternate masculine scripts. Race is often implicated in the discussion of class, but also serves as a unique context in which men learn masculine scripts. It is important to remember that these scripts are not only racialized, but localized as well. Here, the American context specifically is considered.

African-American masculinity has been uniquely affected by the social history of the United States. While some minority racial and ethnic groups have seen greatly increased acceptance into US society, African-Americans, particularly African-American men, still face a great deal of social discrimination, and are limited to particular scripts of masculinity. It is important to recognize that most scholarship on African-American men speaks about impoverished urban African-American men, who face multiple intersecting forms of oppression (Collins, 2004).

Acting as a provider is central to African-American men's perceptions of masculinity, however, African-American men face additional challenges in being able to accomplish this goal (Collins, 2004; Payne, 2006). Although this may seem similar to the problem of white working-class males, African-American men are faced with additional structural barriers to accomplishing this ideal, often competing for the same jobs as white men, while they lack the same skills, education, and must contend with enduring racism (Collins, 2004). These problems often create a conflict for the African-American men, specifically in their romantic relationships. Facing structural inequality, alongside criticism at home for not fulfilling their obligations to the family, creates a great deal of tension between African-American men and women (Franklin, 2001). Here, African-American men and women are placed in opposition to one another, and in order to avoid seen as being controlled by their women; men must exert their control over their women to assert their male dominance. Although these may not be the only possible outcomes, these are the culturally prescribed scripts available to African-American men (Collins, 2004).

Asian-American men have also developed a script to respond to stigmatization by the larger culture. Asian-American men have been stigmatized as both effeminate and sexually impotent by the larger society, denying their ability to fulfill the script of hegemonic masculinity, while simultaneously being upheld as a 'model minority.' In response to these labels, Asian-American masculinity has developed a less rigid masculine script that challenges these cultural messages to varying degrees. Asian-American men explicitly challenge the notion that they are somehow sexually inferior, instead enacting an active and adventurous sexual script. They also challenge the more traditional masculine script by engaging in traditionally feminine tasks, such as housework, but incorporating these tasks into their own masculine scripts. In this way, the Asian-American masculine script is more egalitarian and flexible than other masculine scripts (Chua and Fujino, 1999; Shek, 2006).

Conclusion

Masculine scripts are embedded within layers of social context. While it is possible to tease apart these layers analytically, men experience their gender, race, class, and sexuality simultaneously and in particular social situations. The position of these identities against one another and the uncertainty of social situations in general can create ambiguity for men regarding which script is appropriate in a particular situation.

Though much of the description here is of cultural scripts, these directly impact interpersonal scripts. Cultural messages inform our everyday interpersonal interactions in the broadest sense. We rely on these cultural scripts to provide us general guidelines for action, but it is through our interpersonal interactions that we refine and redefine our interpersonal scripts. Some of these interpersonal scripts exist as general guidelines of social interactions with others in particular social settings, while the interpersonal scripts that we develop in more intimate settings may be highly particularized (Gagnon and Simon, 2005; Simon and Gagnon, 1984, 2003).

At the level of the intrapsychic, cultural scripts shape the hopes, desires, and expectations that each of us carry into our interactions with others. Of course, these cultural messages are internalized in unique and highly individual ways; individuals may embrace these messages wholeheartedly, reject them completely, or, more often, interpret them in their own ways. But in social interactions, people can not only consider their personal desires, individuals must manage these intrapsychic scripts in their interactions with others, choosing when, how, and if they will reveal their personal desires to others who may have conflicting aspirations (Gagnon and Simon, 2005; Simon and Gagnon, 1984, 2003).

Scripting theory allows us to examine each of these levels, and the ways that they interact with one another to gain a greater understanding of the meanings individuals bring into

social situations and how meanings are created through those interactions. It allows us to understand that while masculinities may be socially constrained, they are simultaneously being constructed through social interactions. This creation of meaning through interaction means that these scripts are not static, but constantly being challenged and redefined, leaving open the possibility for alternative masculine scripts to emerge.

Mass Communication: Normative Frameworks

John D Peters, University of Iowa, Iowa City, IA, USA

Abstract

From ancient times, mass communication has always raised normative questions. Most ancient views distrusted mass communication for misleading people from God or truth. Modern views, especially liberalism, endorse mass communication as a means of discovering truth and reaching consensus, but there are many dissents as well. The article examines the ancient and modern frameworks on the ethics and politics of the mass media. Mass communication, the public dissemination of symbols that are in principle addressed to everyone, has always aroused controversy, not only about specific policies and practices, but about larger philosophical questions concerning morality, politics, and art.

Distrust of Mass Communication

Despite its twentieth-century ring, mass communication is as old and fiercely debated as civilization itself. Mass communication will always occupy a symbolically charged spot in any social order, whether its medium of communication be pyramids or stained glass, newspapers or television, word of mouth or the Internet, and whether its aim be to keep subjects in awe, believers in the fold, or citizens informed. The lack of discrimination in audiences and the easy transgression of social boundaries are two key objections to it. Over the past century, such media of mass communication as dime novels, comics and radio, television, cinema, videogames, and the Internet have been blamed for about every ill imaginable, from the degradation of taste to the corruption of youth and the decline of democracy. Though such attacks are motivated by genuine worries arising from modern conditions, they have intellectual roots that reach into the Judeo–Christian and Greco–Roman past.

Normative frameworks with ancient roots are very much alive in both academic and popular debates about the social meaning of mass communication. They often act today more as moral intuitions about what a social order should expect from its public forms of communication than as systematically developed doctrines. Since such intuitions, at their worst, scapegoat mass media and thus invite simplistic causal attributions for complicated social problems, much social research on the effects of mass communication has explicitly contested older moralistic or normative ideas about mass communication. It would be a mistake, however, to assume that such ideas are of little interest to the social sciences. First, these larger frameworks provide the moral and political resources that drive the enterprise of social science as a quest for truth, humane social organization, and political progress. Second, many age-old topics are very much on the academic and public agenda today, such as worries about the role of the image in politics, the socialization and education of children, the possibility of global understanding amid radically incommensurable political and religious views, the ownership of information, or the place and purpose of the arts (see Table 1).

Iconoclasm

What a visually dominated society implies for politics, cognition, and education is a recent concern with a long past. We might start a genealogy of the distrust of the bewitching power

Table 1 Normative frameworks for mass communication

Doctrine	*A characteristic good*	*A characteristic evil*	*Representative theorist*
Iconoclasm	Representational purity	Idolatry	Moses
Platonism	Reality	Appearance	Plato
Christianity	Compassion	Callousness	Augustine
Stoicism	Cosmopolitanism	Anxiety	Marcus Aurelius
Elitism	Quality	Vulgarity	Arnold, Adorno
Republicanism	Public virtue	Corruption	Cicero, Machiavelli
Liberalism	Free inquiry	Censorship	Locke, Jefferson
Right-wing critics (nineteenth century)	Excellence, tradition	Leveling herd-mentality	Carlyle
Left-wing critics (nineteenth century)	Human fulfillment	Domination	Marx
Liberal critics (nineteenth century)	Expressive variety	Tyranny of majority	Mill, Tocqueville
New deal	Public interest	Irresponsibility	Hutchins commission
Social democracy	Public service	Commercialism	Habermas
Neo-liberalism	Free markets	Regulation	Hayek, Coase
Postmodernism	Free play	Hierarchy	Lyotard, Baudrillard
Cultural Marxism	Empowerment	Dominant ideology	Gramsci, Stuart Hall
Communitarianism	Participation	Apathy, disengagement	Dewey, Charles Taylor

of images atop Mount Sinai. The second of the 10 Mosaic commandments proscribes the making of graven images and of mimetic visual arts in general. Ever since, iconoclasm (the smashing of images) has proven to be an enduring theme in the history of thinking about public life (Goux, 1978). Moses was specifically concerned with the proper representation of deity, but the intuition that images mislead hearts away from the 'true' vision or way of life has long had a more general purchase. Monotheism's gesture of casting away the false gods is an early ancestor of the modern scientific idea of sorting truth from error. In cultures influenced by the three ethical monotheisms of Judaism, Christianity, and Islam, notions of idolatry and simulation are still used to describe communications and their dangers. Depictions that are taken to be insulting of sacred things can still cause worldwide outrage and create calls for silence or censorship, such as the Muhammad cartoons controversy started by the Danish newspaper *Jyllands-Posten*. Such calls rest upon the controversial viewpoint that some things should not be represented. From a liberal point of view, such an idea is censorship. But the bitterness of the fights we continue to see and a culture of paparazzi photos and online pornography remind us that restraint in depiction can be a useful lesson. The principled refusal to look can stem not only from cowardice, but from tact and civility, and offers a rich vein for considering ethical dilemmas in media ethics and image ethics (Dayan, 2006).

Fabrications and the Corruption of Youth

Fear of the seduction of youth dates at least to Plato's *Republic*. Plato famously banished poets from his utopia, a gesture archetypal for normative thinking on communication since in at least two respects. First, Plato considered poets imitators who multiply appearances rather than realities in a world that already suffers from an overpopulation of copies. Just so, distrust of media veracity is widespread today, whether in the routine suspicion that some of the news and all of so-called 'reality TV' is fabricated or the far more sinister inkling that the Holocaust was a carefully orchestrated media conspiracy. Second, poets, claims Plato, have a bad influence on the young, even if their falsehoods can be pedagogically useful. Plato's ideas about socialization continue to resonate in debates about mass media, from comics and cinema to popular music and computers. The notion that a just society must patrol public representations appears in the long history of regulating depictions of sexuality and violence in film, and in various content ratings systems for film, television, and popular music. Though some modern interpreters of Plato, most notably Sir Karl Popper, read the *Republic* as the fountainhead of authoritarian thinking, few would deny that mass communication aimed at children deserves special care or that the portrayal of 'reality' is a thorny matter of public importance.

Responsibility to Distant Suffering

Both Stoicism and Christianity teach the idea of moral responsibility to the entire world. The Stoics speak of cosmopolitanism, or literally, world citizenship, and the Christians speak of a love that can encompass the entire human family. In the Christian notion of the Gospel, or literally, the good news, there is the ambition, in principle, of dissemination to a worldwide body of communicants. The hope for a great community on a global scale remains a potent political and moral project today, however much it may be stripped of its religious or philosophical content. Here the features of mass communication that usually evoke suspicion are valued. Its lack of discrimination in recipients and ability to cross social barriers make it potentially an inclusive and just form of communication.

Mass media are prime instigators of responses to distant suffering (Chouliaraki, 2006; Silverstone, 2007). Television, advertising, and documentary film all inherit the long colonial and humanitarian legacy of inspiring care for the wretched of the earth, seen at a distance. Some suggest that foreign policy is partly dictated by the location of television cameras. Victims whose fates can be made graphically visible to influential audiences may, in this argument, be more likely to receive political, humanitarian, or military aid than others who languish beyond the reach of the image. Others suggest that representations of human suffering do not deepen but rather deaden moral sensibilities, as news organizations, fighting for shrinking audiences, push the limits on shock and outrage by packaging suffering for popular titillation in ever more gruesome ways. The question is whether the aestheticization of suffering serves to inspire ethical action or to divert it. In any case, the ability of the media to alert the public to global crisis, to arouse humanitarian interest in those who suffer and to build cross-national bonds of solidarity – or hostility – is clearly one of the most important sites of debate in the politics and ethics of the media today. The Christian and Stoic heritage suggests that the representation of one's fellow humans is an ethical responsibility of the first order. Mass communication cannot act in a vacuum: nothing less in this view than global brotherhood and sisterhood is at stake.

The Degradation of Art

Finally, a tradition with a complex genealogy extending to early modern thinkers such as Montaigne and Pascal or the Roman satirists criticizes mass communication for its cheapness and low level of taste. Often frankly elitist in its condemnation of vulgar taste, commercial motivation, and formulaic structure, the high-art tradition wants communication to be an intense and concentrated aesthetic experience. It is perhaps false to say that elitism offers a normative framework for mass communication at all, since mass communication itself – the fact of widely diffused and openly addressed forms of culture – often seems the prime target. Matthew Arnold's dictum that genuine culture consists of 'the best that is known and thought in the world' or the Frankfurt School's fulminations against the 'culture industry' are two instances of the viewpoint that the arts can be morally and socially redemptive when appreciated in the proper, often rarefied, conditions, but catastrophic when they circulate in a bored and restless mass society. Here art's power prevails only when spread among the few.

An affirmative case for art in mass communication is found in the republican tradition. For Cicero, who stands at the tradition's head, rhetoric is not simply an art for inflating weak arguments and wooing crowds; it is an authentic technique of political deliberation and inspiration. Republicans, often

looking to classical Athens, also argue that theater can be a healthy part of political life, an opportunity for the collective consideration of the most important problems facing the community, not just a tool of deception or manipulation. To be sure, a republican such as Machiavelli has a bad reputation on the uses of rhetoric and theater, but he also understands communicative artistry as the very stuff of public life. Whereas many democratic theorists have distrusted the theater for breeding inauthenticity, fostering fantasies, and silencing the people, republican theorists insist that rhetoric and drama can have a legitimate place in a just polity (Hariman, 1995).

Though concern for aesthetic taste and mass culture was the very heart of the last century's debates about media, culture, and society from the 1920s through the 1980s, changes in education, society, technology, and taste have since weakened the widespread confidence that a canon of works exists whose quality is beyond dispute. High-brow taste has become increasingly omnivorous and elite art hybrid, jumbling heretofore segregated aesthetic levels. Even so, the sense that the products of commercial culture, produced to fill the many-channel environment of cable television and the almost endless bandwidth of the Internet, are often appalling and that mass communication could theoretically be a thing of beauty are not likely to disappear from the agenda (Gans, 1999). The critique of popular taste is not just snobbery about one's neighbors; it can also be a genuine insight about the way society is organized.

In sum, several of the most important intellectual sources in the western world – Hebrew, Greek, Roman, and Christian – have contributed a number of views about mass communication, all of which converge on the notion that the public dissemination of symbols is of such religious, social, moral, and aesthetic weight that it can never be left without some kind of control or restriction. Whether seen as dangerous or valuable, mass communication is held by all these traditions to be powerful indeed.

Faith in Openness: Liberalism and Its Critics

As opposed to the ancient nervousness about dangerous messages, most modern normative thinking about mass communication developed from or in critical dialog with the Anglo–American tradition, central to which is the proposition that public culture serves society best when left to its own devices, without meddling from crown or church. Liberalism, as the tradition has become known owing to its ideal of liberty, emerged from the writings of English Protestant thinkers in the seventeenth and eighteenth centuries, and has spread widely to become the official doctrine not only of communication policy, but of many governments throughout the modern world (where it is often honored in the breach.) Mass communication, liberalism argues, may threaten extant powers or opinions, but is never truly dangerous.

Distinctive in liberal thought is the special place given to freedom of communication, considered not simply one of many valuable liberties, but as fundamental to all others. The marketplace, whether of goods or ideas, is considered a refuge against the power of the state or church. The market's openness, equality, and lack of fakery are held to make it a model of the nature of symbolic exchange as well. Liberals conceive of liberty as the absence of constraint. They abhor censorship. Public toleration of ideas held to be repellent or dangerous is, for liberals, the price paid for liberty and an expression of the faith that truth, in the long run, will triumph. Open discussion, like the open market, is held to be self-correcting. The press, said Thomas Jefferson, 'is the best instrument for enlightening the mind of man' and liberal thinkers often give newspapers – and later mass media in general – a privileged mission in civil society, sometimes to the neglect of other institutions. (The press, as is often pointed out, is the only nongovernmental institution mentioned in the US Constitution.) Liberals dream of the press as a 'fourth estate,' an unofficial branch of government, an all-seeing monitor of society and politics generally, and the public's lifeline of political truth.

The liberal framework, in sum, values openness, criticism, diversity, and liberty in mass communication; enjoins an attitude of vigilance, tolerance, self-control, public curiosity, and rationality on the part of citizens; and believes in a knowable world and in the ultimate fruitfulness of open discussion for societal progress and discovering truth. It owes much to the Enlightenment confidence that scientific progress will banish all shadows and advance society. Because of their strong faith in reason and progress, liberals often dismiss as censorious and no longer relevant the older frameworks discussed earlier (Peters, 2005).

Nineteenth-Century Criticisms and Alternatives

The history of modern philosophical norms of mass communication is largely that of the development and criticism of liberalism. In the course of the nineteenth century, liberalism came under criticism from the right, the left, and from within. From the political right came the charge that liberalism's refusal to identify any positive moral good besides liberty was destructive of tradition and public spirit. Its love of freedom splintered civil society either into private egos pursuing their own interests or herds of bovine citizens haplessly searching for leadership. Such critiques urged that the communication structures shaping public life should not be left to shift for themselves but must be actively cultivated so that the 'best men' and ideas can prevail, and that discrimination can mark out zones of taste.

From within, liberal critics of liberalism such as Tocqueville and John Stuart Mill noted the potential of the liberal trust in public opinion as the ultimate arbiter of political and social life to breed conformity and 'soft' forms of despotism. Tocqueville called for deepened forms of community involvement in voluntary associations, and Mill for a more robust openness and courage in thought and discussion. Both saw the dangers of a tyranny of the majority and the unintended consequences of social atomization. Tocqueville and Mill did see the state and church as impediments to liberty, but their great contribution was to discover subtler forms of democratic degradation – in culture, thought, opinion, and everyday life.

From the left came an attack on the liberal conception of a self-regulating marketplace of goods and ideas. For Marx, most notably, to speak of liberty in the abstract was misguided because it neglected the historical and economic structures that limit the real experience of free expression. Thinkers in Marxist

and socialist traditions have been trenchant critics of the claim that unrestrained discussion will automatically yield truth rather than ideology. Quite like right-wing critics of liberalism, they argue that freedom must mean more than the absence of constraint. Freedom of the press is wonderful, the old quip goes, if you happen to own one. For leftist critics, the liberal equation of trade and discussion helps reinforce massive inequalities in the power to propagate ideas. Freedom of communication must, in this view, include meaningful chances for people to act and speak in public, a point made more recently by the ways that liberal ideas can exclude on the basis of gender, race, class, sexuality, ability, and religion. To achieve the ideal of authentically free communication, citizens need access to the means of communication. More than freedom from censorship, this ideal hinges on people playing meaningful roles in the making of history and in shaping their own political economic fates.

Twentieth-Century Developments

In the twentieth century, fascism emerged from the right-leaning critique of liberalism. European social democracy and the American New Deal developed as left-leaning correctives, with the state in each case assuming an affirmative role in subsidizing social services not delivered by the market, including new mass communication services. In the USA, where the role of the state was weaker than in Europe, broadcasting became a commercial enterprise with light federal regulation. Even so, American broadcasting in theory served the 'public interest, convenience, or necessity.' Though rarely enforced, the public ownership of the airwaves, including the right of listeners to reply and to have programming that met their needs, was found constitutional in several important Supreme Court cases in the USA in the postwar decades.

In Europe, broadcasting developed as an organ of the state, with a different history in each nation (*see* Public Broadcasting). Whereas media in the USA operated in a capitalist system with occasional governmental oversight, in Europe and elsewhere, government or quasi-government institutions were developed to provide information and entertainment to the entire nation. The British Broadcasting Corporation, long seen as the international flagship of public-service broadcasting, rested on such principles as universal service, quality programing, national integration, and rejection of creeping commercialism (often read as Americanism). Public-service broadcasting was one part of the welfare state's program of providing citizens with the common necessities of life (Curran, 2011).

Important theoretical treatises on mass communication in the twentieth century reflect a belief that mass communication should serve the public and not simply be free from constraint. In the USA, an important proposal for reform was *A Free and Responsible Press* (1947), better known as the Hutchins Commission. Its title already tells the story: freedom is not enough; the press must actively contribute to the commonweal and stand responsible for its effects. Highly critical of sensationalistic and shallow reporting, which it traced to the economic conditions that required media institutions to grab rather than educate audiences, the report did not, however, call for the state to intervene in the business of public information. Its answer was professional self-regulation within capitalism. Many journalists received the report with hostility, though the project of private ownership combined with public responsibility prevailed in the best postwar American journalism, both print and broadcast such as news produced by NBC (National Broadcasting Corporation) and CBS (Columbia Broadcasting Service) in their heyday. Here the normative vision combines the classic liberal doctrine of freedom from state interference with an affirmative concern for civic duty.

Perhaps the most important theoretical treatise on the normative grounds of mass communication in the second half of the twentieth century was the German philosopher Jürgen Habermas's *Structural Transformation of the Public Sphere* (1962). It articulates the European sense that mass communication is a social good too precious to be left to the market or the state. Notable about this book is its historical and social contextualization of the project of rational public communication. Habermas's notion of the public sphere is a rethinking of the liberal ideal of publicity (now often called 'transparency') for radical democratic purposes. Whether interpersonal or mass, any act of communication discloses, Habermas believes, the potential of persuasion without violence. Habermas's thinking about mass communication turns on the norm of uncoerced discussion in which the only power is that of the better argument. Rationality and participation are his requirements for just communication; he does not believe that the culture industries (mass media) will do the job. Though his practical alternative is not always clear, his aim is to deepen social democratic ideas and practices of mass communication. Habermas's critics have made many improvements in his model (Calhoun, 1992). But so has Habermas himself, most recently exploring the thorny problem of religion in a secular public sphere.

With the globalization of the world economy and the deregulation of the media in the USA, Europe, and elsewhere in the past decades, classic liberal ideas, 'neo-liberal' or 'market liberal' ideas, have come roaring back in the realm of mass communication. Talk of liberty and the free market has been persuasively used to justify regulating companies producing news and other content for outlets of mass communication. Neo-liberal arguments that have been made for the more traditional media businesses of news and entertainment have generally emphasized one side of liberal doctrine (the lack of state regulation of the market of goods and ideas) over the other (the creation of free, open, and diverse public fora). In arguments made for new or digital media businesses, the opposite is generally the case. A technolibertarian view is the reigning ideology for Internet companies such as Google (Turner, 2006) which argue for the absolute freedom of information (while also making billions from tracking online behavior and choices). Theorists of the cultural and legal implications of the digital domain grapple with a liberal legacy that has been put under duress by new technical and political conditions (Boyle, 2008).

Other Criticisms

A long tradition of social research on the production of news shows how the liberal dream can serve as a legitimating ideology for professional journalists and mask the social reality

of newswork. The sociology of news production shows that journalists follow formulaic routines and organizational cultures that shape their output more decisively than does a fearless quest for truth. The actual content and practices of journalism seem relatively unaffected by liberal ideas of the press. Exalted rhetoric about the free press coexists with a long history of sensationalism that dates to eighteenth-century broadsheets, if not earlier. The production of news is a crucial and fascinating tangle in contemporary politics and culture (Schudson, 2011).

Postmodernism offers another philosophical attack. The liberal model of communication, postmodernists argue, is simplistic, missing the instability of language and the deeply rooted impediments to communication as traditionally conceived. Further, in an age rife with visual rhetorics, censorship should not be the chief worry. Public consciousness can be manipulated not only through the denial of information but from too much information, or information selectively presented or 'spun.' For postmodernists, liberalism's fear of coercion from church or state leaves it unprepared for the simulations and dream worlds that stem from the market or the psyche itself. Not only suppression but seduction shapes the public agenda.

A similar point is made by cultural Marxists: instead of overt coercion, power largely works through the co-optation of consent or the creation of 'hegemony' (*see* Hegemony and Cultural Resistance). The liberal public sphere can serve as a forum of pleasurable domination – a view anticipated, from a different political position, by Tocqueville and Mill. In contrast to the liberal emphasis on dissemination, Marxist-inspired cultural studies often focus on reception: how audiences read messages against the grain of dominant ideologies (Chen and Morley, 1996). Here, the liberal emphasis on active citizens is mirrored, but with a richer, more politicized account of the receiving end of mass communication. As in classical Marxism, neo-Marxists insist on looking at the results, not just the liberties, of communication.

A similar critical approach is found among theorists of race, gender, and sexuality, who show the hidden injuries of the liberal dream of ignoring bodily difference and call, instead, for a more plural politics based on a recognition of the plurality and fluidity of identity and the key role played not only by the dominant public but by 'counterpublics' as well (Warner, 2005).

Communitarians, descendents of nineteenth-century rightist and centrist critics of liberal egotism, have a revisionist program for mass communication. They often assail television as we know it for its alleged stupefactions and sapping of social capital, and in turn call for new forms of news gathering and discussion to invigorate community ties and public involvement. For communitarians, a chief ill of contemporary life is the alienation of ordinary people from public communication or the self-enclosure of citizens inside narcissistic bubbles generated by ever more selective forms of personal news filtering. (In contrast to many who herald the Internet as a beacon of liberty, some libertarians view it as a means to add the process of social fracturing into ever more minute taste publics.) It becomes the task of the press, in this view, among other agencies of mass communication, to draw citizens into the common good and to bring them together into fora in which they bump elbows with strangers. The 'public journalism' movement, which reflects communitarian ideas, calls for the participation of all citizens in open and public dialog. Its normative vision of mass communication is not the liberal free dispersion of ideas but a civic conversation of all with all about the important issues of the day (Glasser, 1999).

Finally, some fault liberalism for its overly rational emphasis. The American philosopher John Dewey, sometimes a communitarian hero, argued that one fault of the liberal conception of mass communication was its dryness. For him, drama in its diverse forms is a key resource in modern society. He believed in an aesthetic education of humans and citizens. Similarly, recent advocates of public service broadcasting endorse entertainment as more than frivolity; it can play a role in widening sympathies for fellow citizens, allowing a sort of communion among strangers. These theorists take artistry in mass communication to be a means of expanded social imagination, rather like the republican tradition. They contest the liberal commitment to the left brain, as it were, of mass communication: the privilege of news in public life. Fiction, they argue, can have as important a civic role as fact (*see* Entertainment).

Whither Media Ethics?

Media ethics has largely developed as a field concerned with the practices of professionals, especially the analysis of hard cases that face journalists (deception, disclosure of sources, the blurry borders of objectivity, etc.). The sheer range and diversity of frameworks reflecting on mass communication and its larger social, political, moral, spiritual, pedagogical, economic, cultural, and aesthetic implications suggest a richer agenda for media ethics. Questions about the tenor of public life, the experience of childhood, the relief of suffering, the possibilities of artistic expression, or the texture of political life in an age of user-generated content, for instance, might take a rightful place in debates about mass communication next to questions about liberty, information, and ideology. Though various normative frameworks may be mutually incompatible in their principles, emphases, or conclusions, each one has something to offer.

Abstract

A social exclusion framework is used to provide a synopsis of literature around the collateral consequences of mass imprisonment for individuals and adult family members. Connections between imprisonment and life course consequences of economic attainments, homelessness, mental health, social disability functioning, subjective status, and political involvement are reviewed. A recent work on mediating mechanisms is identified. Effects on spouses and caregivers are further reviewed in terms of maternal well-being and financial supports. Suggestions for future research on other aspects of spillover effects and mediating mechanisms are made, along with the need for research on the collateral consequences of women's imprisonment.

Mass imprisonment refers to the social and historical increase and concentration of imprisonment in the United States since the 1970s primarily among disadvantaged minority males (Garland, 2001; Pettit and western, 2004; Western, 2006). The most recent statistics show some decreases in state prison populations over the past 3 years but increases in federal prisons (Carson and Golinelli, 2013). However, the major overall trend is of an overwhelming increase in incarceration rates, where the prison population has more than tripled between 1997 and 2007 (Garland, 2001; Pew Center on the States, 2008). Men comprise 93% of prison population (West et al., 2010). Rates indicate that females are one of the fastest growing segments of incarcerated groups (Kruttschnitt, 2010). At present, male imprisonment rates exceed those of females by 14 times (Guerino et al., 2011). In addition to gender disparities, incarceration is disproportionately concentrated by race and class, with young black males with low levels of education having the highest rates reflecting social inequality in society (Pettit and Western, 2004; Western, 2006). Among men, black non-Hispanic males have an imprisonment rate that is seven times higher than for white non-Hispanic males (Guerino et al., 2011). Pronounced racial disparities are also found among females where black non-Hispanic females have an imprisonment rate three times that of white non-Hispanic females (Guerino et al., 2011). Furthermore, in the past decade there has been a growing Hispanic population in prison, where one in every six Hispanic males and one in every 45 Hispanic females born today can expect to go to prison in his or her lifetime. These are double the estimated rates for non-Hispanic whites (Mauer and King, 2007).

Social exclusion is a consistent theme in the work on collateral consequences of incarceration in the life course. Social exclusion implies being 'shut out' from conventional society (Micklewright, 2002). This may include disengagement from key social institutions (Walker and Walker, 1997) as well as broader societal disconnection fostered by health limitations (Aber et al., 2002). Much of the collateral consequences research on mass imprisonment identifies exclusion among former prisoners in roles as workers, citizens, and spouses (Pettit and Western, 2004; Western, 2006; Manza and Uggen, 2006). Furthermore, the majority of adult male and female prisoners are parents (Glaze and Maruschack, 2008). Another consequence of mass incarceration is the social exclusion or disconnection of those affected by incarceration, in the form of spillover effects (Comfort, 2007), including prisoners' families, from major societal institutions (Foster and Hagan, 2007; Murray, 2007). Pettit (2012) identifies a further form of social exclusion of incarcerated groups, and especially disadvantaged African-American males, from many data collection efforts, rendering this group largely invisible to contemporary social science and social policy efforts. We focus on forms of social exclusion and related social and health consequences for adults of mass incarceration in this article.

The literature on the consequences of mass imprisonment most often focuses on adult men given this societal concentration by gender; however, women's incarceration also has various important consequences (Kruttschnitt, 2010; Hagan and Foster, 2012). We therefore attend to research on the incarceration of both men and women, to the extent the research literature allows.

In this article, we review recent evidence pertaining to individual outcomes and the influences of one's own incarceration and its effects on adult family members. Our article begins to identify trends and areas of future research from this developing literature in terms of mediators and moderators of incarceration influences on various life domains in one's own life and of other adults. A critical area of further research concerns parental incarceration influences on children, including their social exclusion as well (Foster and Hagan, 2007; Murray, 2007). Thus we also refer the reader to key overviews that will hopefully stimulate and prioritize further research (Hagan and Dinovitzer, 1999; Comfort, 2007; Murray and Farrington, 2008; Murray et al., 2012; Wakefield and Uggen, 2010; Wildeman and Muller, 2012; Wildeman, 2010).

Individual Consequences

This section reviews the effects of incarceration on a host of life course outcomes for individuals. These include economic attainments, homelessness, mental health, social disability, subjective status, physical health, and political involvement.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45068-3

We highlight some of the most recent work that identifies factors that mediate the association between incarceration and various outcomes. These mediating factors are of particular policy significance, as they suggest the mechanisms through which the problem effects of incarceration are transmitted, and therefore may be socially modified.

Holzer (2009) provides a comprehensive review of studies on the effects of incarceration in the economic realm on employment and earnings. He attends to effects on employers (the demand side) and effects on workers (the supply side). Evidence is fairly consistent on the demand side, showing that incarceration decreases employer demand for those with criminal records (e.g., Pager, 2007). On the supply side, often using data from large-scale survey studies, there is some mixed evidence, but overall this research shows negative effects of incarceration on the earnings and employment of individuals who have been incarcerated compared to those who have not (e.g., Western, 2006). Consequences include lower wage levels as well as lower wage growth. They also include fewer weeks of employment per year and annual earnings (Western, 2006).

Western (2006) further details some of the macroeconomic consequences in American society of mass imprisonment. Central among these are persistent white–black wage inequalities that are found over time when calculations take into account the hidden penal population in the population. When calculations omit the penal population, wage inequalities are seen as decreasing between whites and blacks. When the penal population is included, heightened disparities in men's economic well-being are evident by race and ethnicity. Pettit (2012) further highlights the consequences of the social exclusion of penal populations from official statistics.

Also, recent research on former inmates expands information on racial differences in the labor market consequences of mass imprisonment over the life course (Lyons and Pettit, 2011). African-Americans are disproportionately exposed to imprisonment. Furthermore, African-Americans are more adversely affected by imprisonment spells in terms of hourly wage growth trajectories. While wage trajectories increase for young men after imprisonment, they grow at a slower pace for African-Americans than whites. The evidence thus supports wage divergence by race following imprisonment and compounded disadvantage for African-Americans (Lyons and Pettit, 2011). Future work with women can expand on these findings.

Further investigating linkages between incarceration and social exclusion in the labor market, Pager (2003, 2007) examines whether a criminal record operates as a negative credential that decreases the likelihood of legitimate paid employment. Using a field experiment with an in-person audit methodology in Milwaukee, Wisconsin, Pager sent pairs of testers to real-world entry-level job openings. She used pairs of African-Americans and white testers, all of whom were college students, who were similar within pairings with the exception of a criminal record that was assigned to them. This study showed that for African-American and white subjects, those with a criminal record received fewer callbacks. Furthermore, African-American subjects *without* a criminal record were similarly likely to receive a callback from employers as white subjects *with* a criminal record. African-American males with a criminal record received even fewer callbacks than white males with a criminal record. These results point both to the exclusion of those with a criminal record from paid employment, but also the broader and enduring significance of race in employment discrimination in hiring decisions.

Subsequent research furthers this line of work with African-American, Hispanic, and non-Hispanic white males in New York City (Pager et al., 2009). One component of the experimental audit study in NYC with male subjects applying for entry-level employment positions revealed that a white male *with* a criminal record was equally likely to be hired as a Latino or African-American male *without* a criminal record – similar to the results of Pager (2007) but now further inclusive of Latinos. These results advance our understanding of stigma and racial discrimination in hiring decisions.

The majority of research of incarceration effects in the economic realm uses male samples. However, one study with incarcerated females by Cho and Lalonde (2008) finds little effect on women's employment outcomes. As Cox (2012) observes, these analyses may benefit from taking into account the type of release women have following incarceration, as inmates discharged with community supervision have to maintain employment as part of their release. This may have led to the unexpectedly negligible effects observed. As study cited in Cox (2012) shows in a correspondence test study that previously incarcerated women were 31% less likely to receive a positive response from employers than women who were not incarcerated. Another cite to a study in Cox (2012) building on the work of Pager with men (2003, 2009), reports that African-American women were least likely to receive a positive response from employers. More work is needed on economic consequences to examine female incarceration in a range of sample conditions.

Adding to this literature on economic exclusion is recent work on associations between incarceration and housing insecurity. Using Fragile Families data on a large sample of urban men, a positive association is found between incarceration and housing insecurity (two times higher among the ever-incarcerated than nonincarcerated) as well as homelessness (four times as high among ever-incarcerated than nonincarcerated) (Geller and Curtis, 2011). Furthermore, postincarceration earnings constitute a mechanism through which incarceration is linked to housing insecurity and homelessness. Higher levels of earnings reduce housing insecurity. This analysis suggests a mechanism by which housing problems can be reduced among those with prison experiences in the form of postincarceration earnings.

In the realm of social relationships, research with incarcerated compared to nonincarcerated men has investigated marital relationships and domestic violence. Incarcerated men are less likely than their nonincarcerated counterparts to be married, but are just as likely to be fathers (Western, 2006). The incapacitation effect of imprisonment is also evident in the higher likelihood of divorce for those who have been incarcerated compared to those who have not been (Western, 2006). Marriage has been identified in life course research as a protective factor against criminal activity (Sampson and Laub, 1993[1995]; Laub et al., 1998; Laub and Sampson, 2003). Marriage also reduces the probability of domestic violence among both drug and violent offenders (Western, 2006). Further analyses may reveal whether it is high-quality relationships that decrease the chances of domestic violence (Western, 2006).

Further work examines the robust association between incarceration and marital dissolution among men (Lopoo and Western, 2005; Western, 2006). Massoglia et al. (2011) examine stigma and duration of separation as explanations for the relationship between incarceration and marital dissolution using NLSY79 data on adult males. They find the initial association between ever being incarcerated and marital dissolution is explained by the duration of incarceration. Each year of incarceration increases the odds of divorce or separation by 32%. In comparative analyses with a nonstigmatized group, they also find that the duration of deployment affects the likelihood of divorce among male military personnel. These results combine to support separation arguments. The authors suggest that added investigation of how these mechanisms work in lives of children could reveal the mechanism for intergenerational influences warranting further exploration.

Research on incarceration and social exclusion spans the social institutions of connections to the labor market and families. This literature further encompasses individual health, which may constitute a pathway to societal exclusion. A number of studies link incarceration to mental health problems. Turney et al. (2012) found an association between recent and current incarceration and depression, net of prior incarceration using longitudinal data on men from the Fragile Families and Child Wellbeing Study. Using stress process theory, this article considers incarceration as a primary stressor and socioeconomic status and family functioning as secondary stressors. The latter are considered as mediators of the incarceration and depression relationship among men. Results support a mediational model where current and recent incarceration influences on depression are reduced by socioeconomic factors, in particular, changes in employment and homelessness, and family functioning, in terms of changes in relationship quality with the child's mother. These results suggest pathways through which incarceration affects depression among men.

Among former prisoners, Turney et al. (2013a) examine the role of stigma and discrimination in the incarceration and mental health relationship. They find criminal record discrimination and race and ethnic discrimination both lead to psychological distress as experienced in a sample of recently released formerly incarcerated men in California. These results suggest that in this previously incarcerated sample, discrimination is a pathway through which incarceration is associated with more psychological distress.

Schnittker et al. (2012) further examine the link between incarceration and psychiatric disorders in a national probability sample survey of adults. They find a particularly robust association between incarceration and mood disorders, net of multiple controls. They further investigate whether psychiatric disorders mediate the relationship between incarceration and disability. They find that psychiatric conditions, and particularly mood disorders, mediate this association. This work suggests the potential value of attention by policy analysts to mood disorders in reintegration efforts as well as research on social exclusion.

Several studies support a role of stigmatizing processes as another pathway from incarceration to social exclusion. These studies include social psychological and physical health outcomes. With national data on adult males, Schnittker and Bacak (2013) find that incarceration decreases subjective social status, or one's perception of one's standing in the community, net of a range of controls. This finding is consistent with experiencing incarceration as a stigmatizing process. Furthermore, Wildeman and Muller (2012) comprehensively review linkages between incarceration and health. In particular, incarceration is associated with worse physical health after release, including both mortality and morbidity (e.g., infectious diseases).

Several studies on the incarceration–health relationship highlight the role of stigma and stress-related diseases among other mediators (Wildeman and Muller, 2012). Schnittker and John (2007) find with a large community sample of males and females, across modeling strategies, that those with a longer history of incarceration have more severe health limitations. Some mediation of incarceration history effects is provided by schooling, income, and marital status but not drug use. Massoglia (2008) reports in a broad community survey that incarceration is positively associated with medically diagnosed illnesses strongly related to stress (e.g., hypertension, heart problems, and chronic lung disease) but not illnesses unrelated to stress (arthritis, cancer, and diabetes). He further finds positive associations between incarceration and stress-related self-reported health problems (e.g., chest pain, heart problems, general health problems) as well as infectious diseases (e.g., urinary tract infections and hepatitis or TB). Finally, a recent study addresses spillover effects on health with survey data from NYC, where variability in neighborhood-level adult incarceration rates range from 2.1 to 12.8% (Frank et al., 2013). This research finds that neighborhood-level incarceration rates are associated with individual asthma prevalence, net of individual incarceration history (Frank et al., 2013). However, this macroeffect is explained when individual sociodemographic covariates are added to the model. The positive individual effect of incarceration history on asthma held net of covariates. Incarceration is therefore linked to asthma prevalence among adults.

Finally, an important realm of social exclusion involves political disconnection. One of the definitive studies in this area by Manza and Uggen (2006) finds that among a sample of young adults, being arrested and being in prison or jail, there was a decrease in the likelihood of voting compared to those who have never been arrested. Furthermore, those who vote are less likely to report a range of offenses. Voting privileges may therefore constitute a pathway to social inclusion and civic reintegration that puts former felons back into contact with a major societal institution and fosters desistance from criminal activity.

Together, this work with adults on economics, housing insecurity, relationships, mental health, physical health problems, and political participation suggests persistent associations between incarceration experiences and various measures of adult social exclusion. Given the pronounced gender disparities in imprisonment, a lot of the work on incarceration and social exclusion among adults is conducted with male samples. Some research uses community samples with males and females and other studies examine relationships between incarceration and a range of outcomes with females. However, fewer studies have been conducted with community samples of women. Much of the recent mediational work identifying socially modifiable

mechanisms pertains to work with adult males. More work on mediators is needed with incarcerated women. Future work needs to identify if mediators are generic or gendered in nature.

Family Consequences

This section builds on the above body of work on the social exclusion of the formerly or currently incarcerated to consider social exclusion among their families. We focus here on collateral consequences of mass imprisonment of spouses, families, and caregivers. A number of comprehensive reviews cover recent research on parental incarceration influences on children (Hagan and Dinovitzer, 1999; Comfort, 2007; Murray and Farrington, 2008; Murray et al., 2012; Wakefield and Uggen, 2010; Wildeman and Muller, 2012). Research further connects paternal incarceration to children's social exclusion (Foster and Hagan, 2007), an area that needs additional investigation with attention to maternal influences and life course stages.

Comfort (2007) details the myriad spillover effects extending from a loved one's incarceration on members of his family, including spouses and significant others. Comfort's empirical research (2008) details a process of 'secondary prisonization' encountered by the women attached to men serving time in prison. The women encounter the rules and regimentation of the prison, even in their own homes waiting for calls from inmates and in their letter writing process, as well as in visitation rituals. Although these women have committed no crimes, they intimately feel the reach of the prison in their everyday lives through their connections to men who are incarcerated. Foster and Hagan (2014) detail the support role that women (e.g., mothers, aunts, sisters) also play in the lives of incarcerated women, particularly as this involves child caregiving.

Several recent studies find effects of male incarceration on women's social exclusion from mainstream society. These include effects of male partner imprisonment and mother's well-being and social support. Wildeman et al. (2012) find that recent and distal paternal incarceration is positively associated with maternal depression and maternal life dissatisfaction. The association of recent incarceration with both paternal and maternal outcomes holds net of a multitude of controls, including maternal and paternal characteristics and a lagged dependent variable. Changes in material hardship and changes in mother's parenting stress explain the association between recent paternal incarceration and maternal depression. Changes in relationships and parenting stress mediate associations between recent paternal incarceration and maternal life dissatisfaction. These mediating pathways illuminate how male partner incarceration affects maternal outcomes.

The influence of male incarceration on women's physical health is also seen at the macrolevel in terms of African-American and white disparity in AIDS infection rates. Johnson and Raphael (2009) show that higher incarceration rates among African-American males explain the racial disparity in AIDS infection rates among females. Lee and Wildeman (2013) further theorize the health effects of male imprisonment on female cardiovascular disease. They identify three mechanisms for future empirical research on this anticipated connection: socioeconomic status, family functioning, and stress and mental health problems.

Turney et al. (2012) find that recent, but not current, paternal incarceration reduces the amount of perceived in-kind (e.g., emergency childcare, housing assistance) and small and large financial support available to mothers in the Fragile Families and Child Wellbeing data set, net of numerous controls. Paternal incarceration therefore contributes to social support disparities among families. Thus recent paternal incarceration undermines the in-kind and financial support of mothers, contributing to the isolation of women from social support resources. These findings suggest that better societal supports are needed in the lives of women experiencing male partner incarceration.

In one of the few studies to look at the effects of parental incarceration on caregivers, Turanovic et al. (2012) use a rich and unique data source to examine the influence of both maternal and paternal incarceration on the caregivers of children of incarcerated parents in Arizona ($n = 100$) with information from a broader study they are conducting. Qualitative responses of caregivers are thematically coded and indicate that 58% of respondents experienced a negative effect of parental incarceration while 22% experienced no change and 20% experienced positive changes. Caregivers were more likely to report negative effects concerning paternal than maternal imprisonment. Negative effects included severe financial strains, childcare strains, and emotional effects. Those reporting positive effects referred to parents who had inconsistently been involved in children's lives prior to imprisonment. Those reporting no changes were referring to inconsistently involved parents in the lives of children before imprisonment. Thus the majority of effects experienced by caregivers were in the form of additional financial, childcare, and emotional strains. These kinds of strains were apparent also in the lives of women partners of incarcerated men in the other studies reviewed on familial effects.

Several studies show effects of paternal incarceration on strained family material conditions, similar to what Turanovic et al. (2012) find among caregivers of children of incarcerated parents. Social exclusion further includes economic aspects of disadvantage and deprivation, with significant intergenerational implications (Kahn and Kamerman, 2002). Using the Fragile Families and Child Wellbeing longitudinal data resource, Sugie (2012) finds that recent paternal incarceration but not earlier incarceration is associated with familial receipt of food stamps and the Medicaid/State Children's Health Insurance Program (SCHIP). However, neither prior nor recent paternal incarceration was associated with Temporary Aid to Needy Families (TANF) assistance. Sugie (2012) notes that food stamps and Medicaid/SCHIP are more inclusive support programs for families than TANF. It may be that families experiencing paternal incarceration are prevented from accessing the full array of government programs for material assistance.

Further research highlights the financial strains experienced by families with incarcerated fathers (Schwartz-Soicher et al., 2011). This research examines material hardship or the extent to which families face difficulties in meeting their basic needs (e.g., could not pay rent or mortgage, evicted from home due to nonpayment of rent or mortgage). Across a variety of modeling strategies, these results show that paternal incarceration increases family material hardship. One of the pathways identified suggests that diminished economic resources result from paternal incarceration leading to family hardship. Geller et al.

(2011) further show that paternal incarceration reduces father's material contributions to families, and one route by which this effect is transmitted is through relationship structure. Cohabitating fathers tend to contribute more to children's financial support.

This article has provided a comprehensive examination of the collateral consequences of incarceration for individuals. These are important and attest to a wide range of effects including multiple dimensions of social exclusion. Our contribution then detailed the consequences of incarceration for other family members, a domain that begins to capture 'spillover effects.' Further work on both topics is needed, including work on mediators and moderators of incarceration effects for individuals as well as additional work on spillover effects. In particular, important future research will involve sustained attention to the collateral consequences of mass incarceration in terms of spillover effects on neighborhoods and communities (Clear, 2007; Sampson and Loeffler, 2010), schools (Hagan and Foster, 2012), and children (Murray and Farrington, 2008; Hagan and Dinovitzer, 1999; Wildeman and Muller, 2012).

Abstract

This article describes influences that lead to violence as well as avenues to prevention and reconciliation. The influences include social conditions, the psychological reactions of groups of people to them, and the societal processes they generate. They include cultural characteristics, such as a history of devaluation of a group, past victimization and woundedness, and overly strong respect for authority. Great violence evolves progressively, making prevention possible. The article discusses avenues to prevention, reconciliation as a way of preventing of violence and renewed violence, and the role of active bystanders in prevention.

The primary starting points or instigators for genocide, mass killing, and other mass violence are (1) difficult conditions of life in a society, such as economic problems, political conflict, and great societal changes; (2) intense conflict between subordinate and dominant groups or conflicts involving vital interests; (3) material self-interest; and (4) war, this already intense violence, which makes genocide more likely when other instigators are also present. The first two instigators activate basic psychological needs in people. The resulting psychological and social processes develop in part as means of fulfilling these needs. These processes include individuals turning to a group for identity, scapegoating, and the adoption of destructive ideologies that offer the vision of a better future but also identify enemies.

As the group begins to harm members of another group an evolution follows, with changes in individuals and the group that allow and is likely to lead to increasing violence. The passivity of internal and external bystanders, outside groups and nations, encourages perpetrators. Once violence has begun, actions by the community of nations to halt its further evolution are essential. These can include intense diplomatic efforts by powerful actors, but at this late point often require military action. But genuine prevention means early actions, when conditions that indicate the likelihood of violence are present. It requires actions by both 'internal' and 'external' bystanders.

To understand and ultimately prevent mass violence, like the Holocaust, the genocide of the Armenians, the genocide in Rwanda, the 'autogenocide' in Cambodia, the mass killings in Argentina and Bosnia, and many others, the social conditions, cultural characteristics, psychological processes of groups and individuals that lead to it must be identified. Important questions and issues include What are the motives of perpetrators, how do these motives evolve, how do inhibitions against killing decline? What are the starting points or instigating conditions in particular instances? What characteristics of the cultures and social processes contribute? What is the psychology of perpetrators and bystanders?

An essential source of groups turning against other groups is the human proclivity to differentiate between 'us' and 'them' and the tendency to devalue 'them.' How can this tendency be mitigated? The passivity of bystanders, ranging from individuals to nations, encourages perpetrators. How can preventive responses be promoted? The conception of origins that follows is based primarily on Staub (1989); of prevention on Staub (2011) (see also Charny, 1999; Fein, 2007; Hamburg, 2007, and references below). (**Table 1** shows influences leading to and processes in mass violence, as well as avenues to prevention.)

Instigators of Collective Violence

These are conditions in a society or in a group's relationship to another group that have great impact on people. They give rise to psychological reactions in individuals and whole groups of people, and actions and events in a society or social group that lead the group to turn against another group, often a subgroup of the society.

Difficult Life Conditions

One starting point for mass violence is difficult conditions in a society, such as severe economic problems, great political disorganization and confusion, rapid social changes, and their combinations. These conditions often frustrate the fulfillment of core material needs, for food, shelter, and so on, but probably even more universally they frustrate basic psychological needs – for security, a positive identity, feelings of effectiveness and control, positive connections to people or a group, and a comprehension of reality.

Group Conflict

One type of conflict involves 'vital' interests. Even though these conflicts have objective elements, such as some territory both sides need for living space, the psychological elements are powerful. They include attachment to territory that is part of the groups' identity; mutual devaluation, distrust, and fear; the experience of assault on one's identity (Zartman et al., 2012); at times fear for the group's and one's own survival; and unfulfilled or frustrated basic psychological needs. These elements make the conflict especially difficult to resolve. Another type of conflict is between dominant and subordinate groups in a society. It is demands by the subordinate group for greater rights that can start active violence between the groups that may end in mass killing or genocide (Fein, 1993).

Table 1 The origins of violence between groups, prevention and Reconciliation[a]

A: Starting points	
Difficult life conditions – economic deterioration, political disorganization, great social changes	
Conflict between groups – material, psychological	
War, revolution	
Self-interest as a motivation (e.g., acquiring the resources of an indigenous group)	
Consequences of these starting points:	
The frustration of basic psychological needs	
Individuals turning to a group for identity and support	
Scapegoating	
(Destructive) ideologies	
B: History, culture, and current practices	
Elements contributing to violence (←):	**Elements of prevention (→):**
Devaluation of the other	Humanizing the other
Destructive, exclusive ideology	Constructive, inclusive ideology
Unhealed psychological wounds	Healing of past wounds
Uncritical respect for authority	Moderate respect for authority
Monolithic society	Pluralism (in values, access)
Unjust societal arrangements	Just social arrangements
Lack of freedom – Repression	Eliminating repression
Lack of truth about past events	Complex truth – Moving toward shared narratives/shared history
Passive bystanders	Active bystanders
C: Continuous processes	
The evolution of harm doing (changes in perpetrators, bystanders, institutions, social norms, and culture)	
Reciprocity in hostile actions and violence	*Reciprocity in positive actions*
The ongoing influence and role of leaders, followers, bystanders	

[a]Extended version of Table 4.1 in Staub, E., 2011. Overcoming Evil: Genocide, Violent Conflict and Terrorism. Oxford University Press, New York.

Like difficult life conditions, conflicts between groups can frustrate material needs and also tend to frustrate basic psychological needs. Difficult life conditions often go together with and intensify the impact of group conflict. Dominant groups, faced by demands from a subordinate group, often protect not only their rights and privileges, but also their security and identity, as well as their comprehension of reality, which includes their view of the 'right' social arrangements. They create and hold on to legitimizing ideologies, views of the world and justifications of their privilege. Such ideologies may stress the intelligence, hard work, moral character, and traditions of the privileged group.

Self-Interest

When a subgroup of society is greatly devalued (see below), a superior group may engage in mass killing to advance its interests. Mass killing or genocide of indigenous peoples has often been in part due to the desire to gain land or develop resources where these groups have lived (Hitchcock and Twedt, 1997).

War (and Violent Revolution)

When violence evolves and becomes intense, it can fairly easily spread from its original targets to other targets as well. When the conditions that tend to lead to violence against a subgroup of society exist, such as intense devaluation, a destructive ideology, or past conflict, the violence of war or revolution (Melson, 1992) can spread to such a target. War can also be a cover under which violence against a subgroup of society is perpetrated.

Turning against the Other

Groups could respond to instigating conditions by cooperative efforts to improve conditions or by resolving conflict through negotiation and mutual concessions. Instead, frequently a complex of psychological and social processes arises that turn the group against another and ultimately lead to violence. Individuals turn to a group for identity and security; people elevate their group by devaluing or harming others (Tajfel, 1978); they scapegoat another group for life problems or blame the other for the conflict; ideologies are adopted that offer a vision of a better life (nationalism, communism, Nazism, social equality in Cambodia, Hutu power in Rwanda, and so on), but also identify enemies who must be 'dealt with' in order to fulfill the ideology.

The Evolution of Destructiveness

The group and its members begin to take actions that harm the other group and its members. This begins an evolution. Individuals and whole groups 'learn by doing.' As they harm others, the beliefs and values of the perpetrators and the whole society they are part of change. The processes through which this happens include just world thinking, the resolution of cognitive dissonance, and adaptation. Just world thinking is the belief that

the world is a just place and those who suffer must have somehow deserved their suffering. Cognitive dissonance is the result of a discrepancy between beliefs and actions. To reduce this discrepancy, people devalue further those they are harming and change their views of what is moral in relation to the victim group. They may start with disengagement from their moral values in relation to victims (Bandura, 1999). Perpetrators, and even bystanders, move on to moral exclusion, excluding the victimized group and its members from the moral realm, the realm in which moral values and standards apply (Staub, 1989, 2011; Opotow, 2011). They also replace moral values that protect other people's welfare with values such as obedience to authority or loyalty to the group. Many of them progress to moral transformation. Killing members of the devalued group becomes the right thing for them to do, a reversal of morality (Staub, 1989, 2011). As the evolution progresses individuals change, the norms of group behavior change, new institutions are created to serve violence (for example, paramilitary groups and government offices serving persecution and destruction).

Contributing Cultural Characteristics

Certain characteristics of a culture make it more likely that, in response to instigation, the psychological and social processes that initiate group violence arise.

Cultural Devaluation

One of these is a history of devaluation of another group or subgroup of society. Such devaluation can vary not only in intensity but also in its nature: the other is lazy; of limited intelligence; manipulative, morally bad; dangerous, an enemy that intends to destroy one's own group. A devalued group that does relatively well – its members have good jobs and some standing in the society – is an especially likely victim. Sometimes two groups develop intense, mutual hostility, which may be called an ideology of antagonism (Staub, 1989, 2011). Seeing the other as their enemy, and themselves as an enemy of the other, becomes part of each group's identity. This makes group violence more likely.

Overly Strong Respect for Authority in a Society

This makes it especially difficult to constructively deal with instigating conditions. Accustomed to being led, people are more likely to turn to leaders, even if they lead in destructive directions, and ideological groups. They are unlikely to oppose it when their group increasingly harms another group. They are less likely to oppose destructive leaders and more likely to follow direct orders to engage in violence.

Monolithic (and Autocratic) vs Pluralistic (and Democratic) Societies

The more varied are the values in a society, the greater the extent that all groups can participate in societal processes, the less likely is the evolution toward mass violence. People will be more likely to oppose harmful, violent policies and practices. Democracies (Rummel, 1994), especially mature ones (Staub, 1999) that are pluralistic and have a well-developed civic culture, are unlikely to engage in genocide.

Unhealed Wounds of a Group due to Past Victimization or Suffering

Without healing from past victimization, the group and its members will feel diminished, vulnerable, and see the world as a very dangerous place. At times of difficulty or in the face of conflict, they may engage in what they think of as necessary self-defense. But, instead, this could be the perpetration of violence on others (Staub, 1998, 2011).

Other Cultural Characteristics

A history of aggression as a means of resolving conflict, as well as certain group self-concepts – a sense of vulnerability, or a feeling of superiority that is frustrated by events, or the combination of the two – make violence also more likely.

The Role of Bystanders

The passivity of bystanders greatly encourages perpetrators. It helps them believe that what they are doing is right. Unfortunately, bystanders are often passive, and go along with a system that is becoming increasingly destructive (Barnett, 1999; Charny, 1999; Staub, 1989, 2011). Internal bystanders, members of the population, often go along with or participate in discrimination. As a result, just like perpetrators, they change. Like the perpetrators, bystanders, as members of the same society, have also learned to devalue the victims. They are also affected by instigating conditions. It is difficult for them to oppose their group, especially in difficult times and in an authority-oriented society. To reduce their guilt and their empathy, which makes them suffer, bystanders often distance themselves from victims. Over time, some become perpetrators (Lifton, 1986).

External bystanders, outside groups, and other nations, also usually remain passive, continue with business as usual, or even support perpetrators. Nations do not see themselves as moral agents. They use national interest, defined as wealth, power, and influence, as their guiding value. When they have ties to another country, they tend to support the leaders, not a persecuted group. This has been changing to some degree, especially, in principle and to a limited degree in practice, with new humanitarian laws, a new international court to try violators, the United Nation's general assembly's resolution of the Responsibility to Protect (the responsibility of the international community to protect the citizens of a country if its own government does not). However, in spite of more preventive interventions by the UN (Fein, 2007), there is no system of enforcement and often the world has remained inactive in the face of conditions indicating the likelihood of violence and even in the face of seemingly impending, or already ongoing violence.

The Role of Leaders

It is the inclinations of a population, the result of the joining of culture and instigating conditions that to a substantial degree

create the possibility and likelihood of mass murder. The people select, or are willing to follow, leaders who respond to their inclinations and fulfill their needs.

But leaders and the elite have an important role in shaping and influencing events. They scapegoat and offer destructive ideologies, and use propaganda to intensify negative images and hostility. They create institutions, such as media and paramilitary groups that promote or serve violence. Often destructive leaders are seen as acting only to gain support or enhance their power. But leaders are also members of their society, impacted by life conditions and group conflict, and, at least in part, act out of the motives and inclinations described above.

Other Influences

One additional influence is a sudden shift in government, combined with 'state failure,' the new government failing to deal effectively with problems that face the society (Melson, 1992). An ongoing war, especially a civil war, also adds to the probability of mass killing or genocide. Economic interconnections between a country and other countries make genocide and mass killing less likely (Harff, 2003).

Halting Persecution and Violence

Once violence against a group has become intense, halting it requires action by nations and the community of nations. Early warning is important, but it only has value if it leads to action. Often, as in the case of the genocide in Rwanda in 1994 (des Forges, 1999), when information about impending violence is available, the international community does not respond. For this to change requires changes in values, and actions by citizens leading governments to build institutions that activate responses by the community of nations. Institutions within governments that have the responsibility for prevention, and connections between these, the UN, and regional organizations are needed.

Appropriate actions include diplomatic efforts: to warn perpetrators, as well as to offer mediation and incentives to stop violence. These must be accompanied, as needed, by withholding aid, by sanctions and boycotts – ideally designed to affect leaders and elites – and the use of force if necessary. To prevent rather than halt violence, to avoid crises, and the need to use force requires early preventive actions when conditions exist that are likely to lead to mass violence (Carnegie Commission on the Prevention of Deadly Conflict, 1997; Hamburg, 2007; Staub, 1999, 2011).

Prevention and Reconciliation

Effective prevention often requires joint effort by internal and external bystanders. External actors can be instrumental in activating internal actors. Unfortunately, the international community rarely responds to indicators of *potential* violence (Hamburg, 2007; Staub, 2011).

Reconciliation between hostile groups can prevent violence in the first place; reconciliation after violence can prevent renewed violence (Staub, 2011).

Creating positive connections between groups, significant contact between members of hostile groups in shared efforts on behalf of joint goals, helps people overcome past devaluation and hostility (Pettigrew and Tropp, 2006). Coming to understand the other's history and culture can also contribute. Democratization (Rummel, 1994), which creates pluralism, moderates respect for authority, and tends to lessen differences in power and privilege, is important for prevention.

Helping to heal both previously victimized groups and members of perpetrator groups – who are wounded, at the very least, by their own violent actions or by their inaction in the face of their group's violence – reduces the likelihood of new or renewed violence. Testimonies, commemorations, especially if they also focus on a positive future, are among processes of healing. Establishing the truth about what happened in cases of prior collective violence, and groups moving toward a shared history, in place of conflicting narratives about who did what, also helps with reconciliation and peace. Assumptions of responsibility and expressions of regret by perpetrators, which are usually difficult to bring about (or mutually, when violence was mutual) further healing, forgiveness, and reconciliation. The punishment of especially responsible perpetrators (but not revenge on a whole group) is important (Staub, 2011). Improving people's economic situation, through equitable economic development of a country, can also diminish the likelihood of violence.

Understanding the influences that lead to violence between groups, as well as avenues to prevention and reconciliation, can have important positive effects. They can increase both resistance to instigating conditions and openness to reconciliation. They can motivate active bystandership in the service of prevention and building a peaceful society. Such understanding can be promoted through workshops and trainings, as well as through educational radio programs, as this was done in Rwanda (Staub, 2011; Staub et al., 2010). Finally, but importantly, the positive socialization of children, the development of inclusive caring, caring that extends beyond the group, and moral courage that enables people to resist destructive influences, are also essential for long-term prevention (Staub, 2005, in press). (See **Table 1** for an overview of approaches to prevention.)

Future Directions

This article has reviewed influences that lead to varied forms of mass violence. Further research ought to consider whether specific forms of violence, such as government persecution, conquest, revolution, civil war, and others, which may ultimately lead to mass killing, also have specific or unique determinants (Totten et al., 1997). Testing our capacity to predict group violence is important. So is the development of techniques to help groups heal and reconcile (Agger and Jensen, 1996; Staub, 2011). Creating positive bystandership by nations and nongovernmental organizations is essential for prevention. Citizen involvement is required for this. When this happens, the effects of different types of bystander behavior need to be assessed. To create a less-violent world, the development of knowledge in this realm and its application has to go hand in hand.

Abstract

Mass media are media of communication such as the printed press, cinema, radio, and television that address large and diverse audiences. Cultural identity refers to a set of qualities attributed to given populations, often thought of as static but which change through time. Mass media have played a key historical role in shaping national cultures and therefore a range of cultural identities. The press, cinema, radio, and television have successively impacted on cultural and national identities within the international system of nation-states. An account is offered of Europe's century-old concern about 'Americanization' through Hollywood films or US television programs. The Third World's interest in a New World Information and Communication Order to redress the unbalanced global flow of news and entertainment is discussed. Media imperialism is considered in relation to the defense of cultural identity and national sovereignty. An account is given of the trade dispute between the USA and the EU over the cultural status of audiovisual products, showing the connection to ideas of cultural identity. Finally, examples of relationships among mass media, language, and cultural identity are presented. The article concludes by noting that 'globalization' will not eliminate the diversity of cultural identities.

The term 'mass media' refers to media of communication such as the printed press, cinema, radio, and television which have characteristically addressed large and diverse audiences. The term 'cultural identity' refers to the attribution of a given set of qualities to a particular population. A cultural identity is not static and eternal but rather changes through time. Cultural collectivities commonly think of their identities in terms of how they differ from others. Distinguishing 'us' from 'them' is therefore central to groups' cultural self-identification. In this article, the relationship between mass media and debates about cultural identity is examined.

How Mass Media Relate to Cultural Identity

Throughout the history of mass communication, there has been a continuing interest in the relationships between mass media and cultural identities. This has been driven by the general, underlying assumption that different media variously form, influence, or shape collective identities as such. How mass media might, at various times, specifically affect the formation and maintenance of national cultures and identities has occupied center stage in this continuing discussion. National identities normally embrace a range of cultural identities based on ethnic, religious, and linguistic diversity. Nationalists, however, often wish to portray national identity as based in a single culture. Nation-states remain, for the most part, the political frameworks in which claims about cultural diversity and expressions of cultural identity within a given society are pursued. Nevertheless, cultural identities may transcend the state system, as for instance in the case of systems of belief that unite members of the world religions. Diasporic communities also share cultural identities despite belonging to different nations and holding diverse citizenships (Schlesinger, 1991, Hall and du Gay, 1996).

Mass Media and National Identities

From a historical perspective, mass media have been an important part of the nation-building process. Successively, the press, the cinema, radio, and television have been invoked as shapers of collective consciousness, as the bearers of a collectivity's culture, or as objects of policy for shaping collective identities. To the extent that the mass media have contributed to the construction of national cultures, they have also necessarily played a role in the creation of national identities, which are still the most important forms of modern cultural identity in the new millennium.

In the latter half of the nineteenth century, the development of a popular press, nationally distributed magazines, and news agencies making use of the telegraph reinforced the creation of national communication systems in countries such as the USA, the UK, and France. Mass communication developed intensively within the boundaries of national states and through widespread, cross-class consumption, it contributed to the creation of common space for public debate, a shared political agenda, and that sense of collective belonging that characterizes national identities (Carey, 1989). Mass communication has therefore played an increasingly central part in the formation of national political cultures. The latter part of the nineteenth century also saw the first major steps in the development of what would come to be a worldwide communications capacity carried through the spread of telegraphy and subsequently telephony in part in line with European imperial expansion. These nineteenth-century beginnings have proved to be the foundation stones of the developing global communications infrastructure which has become steadily more relevant for debate about the development of transnational cultural identities at the end of the twentieth century and at the start of the twenty- first.

Audiovisual Culture

The rapid growth of the cinema before and up to the First World War inaugurated an era in which the moving image ultimately came into its own as the globally dominant cultural form. From its inception, the cinema developed as a national cultural institution. It provided images of the people and,

through stardom, of popular icons of identification that played into the elaboration of national identities by representing a culture. At the same time, however, the early cinema was also an international medium that addressed diverse audiences across the boundaries of nation-states. This duality has made the relationship between the moving image and the maintenance of cultural identity within the territorial boundaries of the nation-state an especially potent issue for many countries.

Since World War I, the role of Hollywood in the international cinematic marketplace has been of prime importance. What has accompanied this primacy has been a widespread concern, long articulated in Europe by politicians and cultural elites from the 1920s onwards, about the impact of 'Americanization' – the exporting of US cultural values, tastes, attitudes, and products – on national cultures and identities. The most vociferous critics have seen the transnational flow of the moving image as an instrument of a US government policy intent on global cultural domination. Other detractors have seen 'Americanization' as the unintended outcome of a successful model of production that invites competition as a mode of self-defense.

Given its salience, it is hardly surprising that throughout the twentieth century 'Americanization' has repeatedly come to the center of public debate. Looked at from the vantage point of elites, it has been identified with the reshaping of popular culture and seen as having a negative impact on actions, beliefs, and identities, especially among young people and the working class. For such groups, American cultural forms have been a key source of pleasure: they have embodied modernity and an escape from a dominant version of national culture.

Although Hollywood's output has often been the principal point of attack, there has also been a much more diffuse concern among national elites with the effects of consumerism on the moral fabric of their societies. So, for instance, jazz and rock, fast food and Coca Cola, shopping malls and coffee bars, advertising and blue jeans have each, at times, come to represent the threatening and transformative ubiquity of America to disconcerted moral guardians. The cultural challenge constituted by 'Americanization,' moreover, has also gone deeper into the social fabric to encompass the challenges represented by the economic model of free-market capitalism. This has long been seen as inimical to the social solidarity ideally aspired to by European welfare states. Not surprisingly, then, the history of US market dominance and cultural anxiety in recipient countries has played into intercultural relations across the Atlantic. It also shaped the wider, global debate about cultural and media imperialism.

Alongside the rise of the cinema, the development of nationally based radio broadcasting in the inter-War years and through to the 1950s ensured the dissemination of a range of genres – drama, music, news, comedy, sport – that addressed segments of nationally constituted audiences. Radio domesticated national culture, defined national public spheres, and ensured that cultural identities became deeply mass mediated in many respects.

The audiences for radio and, later, television shared a public world which persisted for most of the twentieth century. The classic vehicle for explicitly pursuing the role of televising the national culture from the 1950s onwards was public service broadcasting, of which the British Broadcasting Corporation (BBC) has been the key model, broadly replicated in many countries (Scannell and Cardiff, 1991).

Before its networks and channels began to fragment and specialize with the diversification of distribution systems, general broadcasting offered a container of common mediated experiences to its audiences and articulated these with other forms and sites of cultural consumption. Formally, through the education system, learners would encounter variants of the national folk history and absorb key literary reference points that in combination offered marks of collective identity and thereby constituted collective memories. More informally, outside the sphere of broadcasting, whether as citizens or consumers, people encountered the national cultural gamut in all its variety. This included recorded and live music, popular comedy, theatrical performances, and national and local sporting events. State ceremonies and religious celebrations punctuated the calendar. By both complementing and re-engineering these cultural forms into its own output, broadcasting invited listeners and, later, viewers into a new relationship of social communication. It offered shared ways of speaking and looking that became an integral part of everyday life. It invented schedules that structured temporal patterns and genres that shaped cultural expectations.

Although its transmissions are no respecters of political or cultural boundaries, for the most part radio has been experienced by listeners as a national medium. However, it has always played an important transnational role in wartime propaganda, whether in the hot war of World War II or during the Cold War from the late 1940s until the turn of the 1990s. And music radio has always had strong cross-border attractions, sustaining international communities of taste.

Besides public service systems, commercial systems of broadcasting such as the US networks – ABC, CBS, NBC – both in their heyday and since, have also had a profound impact on the mediation of national culture by way of providing a wide range of televisual forms. US programs have been pre-eminent in defining the international experience of television for many countries. National television systems, and latterly subscription-based movie channels, moreover, have been important vehicles for the dissemination of cinema, especially of Hollywood's output, which has thereby reached a global audience alongside distribution via the theatrical circuit and through the sale and rental of video recordings.

As the ways in which television was distributed rapidly diversified in the 1980s and 1990s – with the growth of cable and satellite broadcasting, alongside the original terrestrial systems – the relations between cultural identity and the medium became more complex. The national audience's experience of television consumption began to fragment. These changes ushered in the crisis of public service broadcasting in many countries. Fragmentation of the national television experience is likely to be further accentuated as digital signals increasingly replace analogue transmissions, and as the range of channels on offer multiplies rapidly in the most developed parts of the world. It is also going to be affected in increasing measure by the delivery of radio, television, and music over the Internet, as these will impact on the range of available choices and bypass broadcasting schedules.

Cultural Identity, Mass Media and Cultural Imperialism

The debate about the impact of mass media on cultural identity increasingly rose up the policy and academic agendas in the 1970s. This coincided with the new interest being taken in the cultural impact of films and television programs that were crossing state frontiers. Shaped by the political contours of the Cold War, in which the strategic interests of the capitalist West were both symbolically, and in reality, opposed to those of the communist East, the debate was greatly stimulated by the postcolonial and postimperial interest in the influence exercised over the rest of the world of cultural production deriving from the main capitalist states (Tomlinson, 1991).

International Debate on Cultural Identity

Discussion centered on the work of the United Nations Educational, Social and Cultural Organization (UNESCO) and on that of the critical writings of media scholars such as Schiller (1969) and Mattelart (1979). In the early 1970s, the first major studies of international television flows were published and academic debate about the significance of audiovisual trade intensified. In Latin America, which became the key locus for critical thought, arguments centered on the economic and cultural dependence of Third World states on those of the developed First World and the perceived threat posed to indigenous cultures and identities by popular media and consumerism.

UNESCO's interventions stimulated a critique of US cultural and media imperialism. The role of journalism (not least US-, UK-, and French-owned international news agencies) was central to this debate. The news agencies were seen as exercising monopolistic control over news flows and as screening out 'south-south dialogue.' Arguments centered on the worldwide impact of the consumption of Western cinematic and televisual fiction as well as that of news. To counter media imperialism, its critics proposed that a New World Information and Communication Order (NWICO) be instituted. The idea of such an international order implied the existence of a transnational communicative space that should and could be regulated in the interests of more equal dialogue. The defense of national cultures in weak and dependent nations and the pursuit of equity and balance in the flow of reports and images in international cultural trade reached its high-water mark in the UNESCO-supported MacBride report (MacBride, 1980). This debate prefigured later attempts to discuss the conditions for creating an international public sphere of open debate (Habermas, 1997).

Supranationalism and Cultural Identity

The defense of national cultural identities by nation- states has remained on the international media research agenda, and not just in the Third World. The European Union (EU) has been a key test case for thinking about the relationships between mass media and cultural identity. The EU is the outcome of a half-century-long process dating from World War II, in which previously warring states have sought to develop a framework for political and economic integration. By the end of the twentieth century, 15 European states were bound together by treaty as a trading bloc in the global economy, with a growing line waiting for accession. Official thinking in the EU has assumed a strong causal connection between media consumption and cultural identity. The desired shaping of a new, 'European' cultural identity has been linked to the formation of a supranational political public sphere and a common citizenship.

EU policy-makers' views on imports of US audiovisual products have strikingly echoed arguments aired in the NWICO debate: from a cultural perspective, the flow of films and television programs has been represented as a threat to European identity. As noted earlier, ever since World War I, political and cultural elites in Europe have been concerned about the impact of American films on their national cultures and identities (Jarvie, 1992). The original national focus has been easily transposed into official, supranational preoccupations about 'European culture.'

The cultural case for domestic film-making has been that home-made moving images represent the nation and invite its members to see themselves as part of a community with a common culture. As television broadcasting became a cultural force across Europe from the 1960s on, official and industrial worries about US dominance of the box office extended to the small screen. There has also always been a major economic interest in limiting imports and safeguarding jobs at home. Hence, the EU successfully negotiated the 'cultural exclusion' of audiovisual services from the final settlement of the General Agreement on Trade and Tariffs (GATT) in 1993. The USA did not accept this principle and the issue remains on the agenda of the successor World Trade Organization.

The EU has found it impossible so far to create a single European cultural marketplace for the moving image. The aspirations have stretched no further, and reasonably so. That is because in the case of radio, television (imported entertainment aside), and the press, cultural preferences have remained predominantly national and regional, following the contours of states and languages. There is no reason to think that this is going to change, even though English is increasingly widely diffused as a second language.

Despite their political convergence, European states still offer a bulwark against widespread cultural homogenization. Publishing, the press, radio, and national education systems continue to sustain diversity and difference in each country. Perhaps it is not so surprising, then, despite some relatively modest investment in financing cross-national film and television coproductions, in supporting producer training and distribution, and in enforcing the provisions of the EU's single-market legislation, that there is little evidence of the growth of a major transnational audience for European audiovisual products. Both national and transnational patterns of cultural consumption co-exist. So, at the start of the new millennium, despite 15 years of policy intervention, Hollywood still provided the common audiovisual diet, with national cinema an also-ran everywhere apart from France, where cultural protectionism had been most vigorously enforced.

Although a supranational polity, the EU is based on nation-states that seek to maintain their distinctive national cultures. The EU's integration process has stimulated a reassertion of regional identities, thereby undercutting the hegemony of nation-states. In some instances, these regions are also 'nations without states' such as Catalonia and the Basque Country in

Spain, and Scotland and Wales in the UK. There, regionalism is inescapably connected with the protection of national and cultural identity. Particular importance has been attached to the role of indigenous mass media in sustaining distinct national cultural identities within the wider state.

Mass Media, Language, and Cultural Identity

National media systems have been crucial disseminators of standardized vernaculars. Anderson (1991) has suggested that the convergence of capitalism and printing created the conditions for the dissemination of secular vernaculars in the early modern period. 'Print language' allowed national languages to be disseminated through markets for books and newspapers, creating a common culture. Audio and audiovisual media have performed a similar role in reinforcing the national idiom. For instance, it was not until the post-World War II period that the majority of Italians came to speak standard Italian, and this was substantially due to the role of radio and television broadcasting, reinforcing and complementing the earlier influence of the cinema. Similarly, in Latin America, it was the mass media that first gave audiences images of themselves that they could connect to their everyday life experiences, offering them an entry point into the national culture and the political public sphere. The mass media also provided the idioms of a common culture. Key instances were the Mexican cinema of the 1930s to 1950s, Argentinean radio drama from the 1920s to the 1940s, and popular journalism in Chile from the 1920s to the 1950s (Martín-Barbero, 1993).

Although mass media have had a homogenizing impact within national boundaries, in some places they have been used to ensure language diversification. This has depended on the political efficacy of language activists seeking access to the media. Success or failure has depended on the status of the language concerned, the amount of political support for broadcasting or otherwise disseminating a language, whether a language campaign has been effectively led, and the state authorities' willingness to encourage linguistic diversity.

Many European states regulate their broadcasting systems to ensure that minority and 'lesser-used' languages are assured of airtime and thereby encourage and sustain a diversity of cultural expression and identities. The policies of individual states have been supported since 1992 by a European Convention on regional or minority languages and in several cases – notably in the Basque Country and Catalonia in Spain, Wales in the UK, and among the Sami of Scandinavia – minority-language broadcasting appears to have been successful in sustaining their language communities. However, Europe is by no means unique. Movements aimed at securing both public support for, and state endorsement of, indigenous radio and television production have been active in Australasia and the Americas (Browne, 1996).

Canada has been an especially illuminating case of the complex inter-relations between linguistic and cultural identity considerations as the Canadian state has fought its identity wars on two fronts. Externally, the country has had to define itself politically and culturally against the USA. Internally, Canada has had to deal with the continuing debate over the status of Quebec, where claims to sovereignty have long been argued in terms of a distinctive national cultural identity (Collins, 1990).

By the middle of the twentieth century, the advent of television extended the existing US media penetration of English-speaking Canada by print and radio. The presence of American media has long shaped Canadian policy-makers' understanding of broadcasting as essential to the maintenance of national identity and cultural sovereignty. As commercial television developed alongside the public sector, governments tried to regulate the system to ensure that Canadian content was carried by Canadian broadcasters, alongside highly popular US material. Consequently, in line with this protectionist stance, when Canada negotiated the North American Free Trade Agreement (NAFTA) with the USA in 1993, it sought successfully to ensure the 'exception' of its cultural industries from the treaty (McAnany and Wilkinson, 1996). This paralleled the EU's approach to GATT, for similar reasons.

While the establishment of public service broadcasting in Canada was in part a response to the commercial model prevailing south of the border, it also took the form of reinforcing the country's cultural and linguistic fault-line between Anglophones and Francophones. Although Francophone broadcasting has sustained the national cultural identity of French speakers, this has run counter to the Canadian federal government's attempts to create an overarching political and cultural identity.

Such tensions have also been experienced in the heartland of global media production, the USA. The major migratory impact of Hispanics has transformed the cultures of states such as California and Florida and has provided the market conditions for the development of Spanish-language television channels with a national reach. This assertion of cultural and linguistic difference has provoked debate about the unique position of the English language in the USA and how multiculturalism relates to a common national identity.

Globalization and New Cultural Identities

In the twenty-first century, the impact of transnational and global changes on what are still largely nation-state-bound systems of communication is likely to increase (Castells, 1997). Ideas of communication sovereignty rooted in the heyday of the nation-state are increasingly difficult to sustain in the face of cross-national media mergers, the development of supranational polities such as the EU, and the rapid, if unequal, diffusion of access to the Internet with its capability of making global communicative connections. Although the worldwide flow of information and cultural products has now permeated the boundaries of states in unprecedented ways, such 'globalization' does not mean that the world is becoming uniform. On the contrary, the reshaping of communicative spaces worldwide means that new cultural identities will emerge continually within, and across, the existing international system of nation- states.

Mass Media and Politics

Abstract

Since the emergence of political science as a research discipline, the influence of mass media on political behavior and political institutions has been well debated, with numerous conflicting and complementary theories proposed to explain how the Fourth Estate reports, interprets, analyzes, and contextualizes information about government and public affairs. In the late twentieth and early twenty-first centuries, technological advances in computers and communication, the reorganization of commercial media operations, and the use of communication professionals skilled in marketing and message manipulation have triggered reconsideration of the roles and functions of mass news media in a world of multiplying news sources and fragmented audiences.

Behavioral Effects and Institutions

From the attempts of sociologists to explain the appeal of totalitarian regimes through their use of mass media, to current efforts to understand the political effects of a worldwide network of interpersonal relationships through Internet and wireless technologies, the study of politics and mass media has developed through investigations of two sets of relationships. One branch of research explores mass media effects on the behaviors of political participation, electoral choice, and policy choice. Another branch examines the impact of the mass media, specifically news media and organizations, as a set of political institutions within a democratic framework. Both effects and institutional approaches are framed within democratic theory, which recognizes the need for citizen knowledge of public affairs and government as a foundation for effective political choices. An understanding of public affairs, diverse political interests, and the general structure of the political system provides the basis for electoral choices involving candidates, efforts to influence policy choices, and citizen participation that ultimately endows legitimacy on a political system.

Theoretical Origins

At the beginning of the twentieth century, mass media could be defined entirely by the concept of the press. The high-speed printing press made possible the production of large numbers of local newspapers. While the telegraph and telephone had enabled accelerated news gathering over great distances in the United States, Europe, and the rest of the world, the production of news in the United States was almost exclusively local. The newspapers were almost exclusively locally owned, and the families and corporations that operated these newspapers were integrated economically, socially, and politically into their communities. The exception was national and international news cooperatives that circulated stories of broader geographical reach and national and international scope.

Real concern about the political effects of mass media first emerged with the use of radio propaganda during the First World War and the post-war creation of radio networks both in the United States and abroad. Of particular concern to sociologists and democratic scholars was whether the use of radio and other mass media in Nazi Germany and the Soviet Union allowed regimes controlling those media to manipulate their populations toward totalitarian ends. The result was a new interest among social scientists in how mass media functioned and how it affected the democratic process. Walter Lippmann (1922) pioneered this connection in his book on public opinion, but it was Harold Lasswell's formulations in the 1930s that sketched the five-point analytical framework for communications. Lasswell's analytical construct (1969) defined the message sender, message content, the message recipients, the communications channel, and the effects as key elements in the communications process.

The initial supposition of public opinion- and propaganda-based studies was that the mass media or message sender injected a political message into an audience of passive message recipients, with effects that varied by recipient according to internal interaction of the message with existing beliefs and attitudes within the individual. These interactions can produce different understanding of the same message. This hypodermic model of communication describes a one-step flow of communication between the mass media and its audiences that predicts powerful effects of the news media.

Mass Media and the Flow of Information

The problems with that model were revealed by a series of elections studies conducted by the Columbia sociologists working with Paul Lazarsfeld. In their study of Erie County, Ohio, in the 1940 presidential election, Lazarsfeld et al. (1944) questioned a panel of respondents seven times, finding that only a few voters changed their minds during the campaign. Lazarsfeld et al. found that the changes had far less to do with campaign news and campaign communications than it had to do with the influence of family and friends. Similar findings in a 1948 study of Elmira, New York, during the 1948 presidential campaign (Berelson et al., 1954) dented the idea that media coverage of presidential campaigns could persuade large numbers of voters. In response, Katz and Lazarsfeld (1955) developed a new model of a two-step flow of communication to emphasize the importance of interpersonal communications. The two-step flow of communication begins with messages disseminated through the mass media. However, rather than being directly received by an audience of

individuals who are attentive, the messages are received by a layer of opinion leaders who are interested and engaged in public affairs. Opinion leaders absorb the messages from the mass media, recast and reinterpret the messages, and through personal connections, pass them along to an audience that is often distracted, unaware, or uninterested in political matters.

The two-step flow model has been criticized from several angles. First, from its formulation, there was little empirical evidence supporting personal contact as the major step in the transmission of ideas and opinion about public affairs (Gitlin, 1978). This lack of empirical evidence led Robinson (1976) to point out that the hierarchal downward flow of information in the two-step model did not reflect research findings that opinion leaders were often engaging in discussions among themselves. Not only were there horizontal cross flows of information and discussion, in some cases evidence supported a direct one-step communication of information from the mass media to non-discussant audiences. The lack of evidence also led Bennett and Manheim (2006) to conclude that mass media has direct rather than mediated effects on its audiences, a conclusion that reverberates in the fragmented media marketplace of the early twenty-first century. With a plethora of channels for delivering news and political messages outside the control and mediation of the mass media, candidates, parties, officeholders, government agencies, and interest groups are often original, exogenous sources for public affairs information and opinion, communicating directly with members of the general public through live video feeds, Internet connections, and interactive cell phone applications. With the recent emergence of punditry-based public affairs programming, the mass media itself appears in the role of a message mediator rather than a message sender.

Diana Mutz (1998) proposed another theoretical challenge to the two-step process. In *Impersonal Influence*, Mutz drew a dichotomy between the pre-television studies of mass media effects and the larger national scope of the broadcast and cable television era. She rejuvenated a key role for the mass media in the political and public opinion process. Mutz argues that the mass media is the primary source for individuals' perceptions of mass collectives, that is, the polity. In other words, where personal relationships may influence personal attitudes and beliefs far more than mass media, the mass media nonetheless influences sociotropic perceptions of the political environment and informs each individual what others are thinking about.

The arguments for a one-step flow of information from the mass media to audiences re-emerged with changes in communications technology and the resulting expansion of news sources and news interpreters. While television news still follows a traditional model of delivering information and context, live video feeds over the Internet or a cell phone place images of events directly before audiences, often without context or interpretation, and with immediate emotional effect. Moreover, the Internet, social networks, and cell phone communications make it easier than in the past for political actors to bypass the news media entirely and send "blast" or targeted information to individuals and groups.

Yet the modern information environment also provides footing for the two-step model: blogs, text feeds, and social network sites providing a broad-based horizontal flow of information among friends and acquaintances. These mediating discussions take place outside the traditional structured news gathering and deliberative forums of the mass media, and their content is unconstrained by professional journalism standards of confirmation, objectivity, and balance.

Audience-Centered Effects

Another upshot of the Columbia school's electoral research was the development of the theory that mass media produced only minimal effects on citizens. This finding attained wide acceptance after the publication of Joseph Klapper's exhaustive review of communications studies (Klapper, 1960). While assuaging fears that media was not unduly influencing American politics, the persistence of the minimal effects conclusion constrained research on the nexus of politics and the news media into the 1990s. Subsequently, much research was conducted to explain why the news media had so little influence on the political choices of individuals. One answer to that problem was the development of theories of selective exposure which argued that individuals would selectively expose themselves to mass media that agreed with their existing beliefs and predisposition. Klapper used this behavior to explain the minimal effects of communication, just as Berelson et al. (1954) used selective exposure to explain why political campaign communications transmitted through the mass media mainly reinforce and mobilize existing preferences rather than persuade the individual voter. Sears and Freedman (1967) contested these interpretations. In a review of previous studies, they argued that there was some evidence for *de facto* selectivity on the part of the mass media audience, in large part because the general audience comprised an overrepresentation of persons sympathetic to the views being expressed. Put another way, the social environment of an individual is likely to provide reinforcement leading to *de facto* selectivity in choosing news sources. On the other hand, there has been little research support for the hypothesis that individuals seek to avoid conflicting viewpoints and information. However, German experimental researchers (Fischer et al., 2005) found that when limits were placed on the amount of information that could be searched for or when subjects received hints of information scarcity, they became more selective in their exposure to information. The researchers concluded that information scarcity emphasized need for quality information and led subjects to select supporting information.

Selective exposure in campaign settings was examined by Iyengar et al. (2008) with an experimental design during the 2000 U.S. presidential campaign, which found varying support for selective exposure hypotheses. One hypothesis, namely the anticipated agreement hypothesis, suggested that people seek out information about candidates with whom they expect to agree and avoid information about candidates with whom they anticipate disagreement. The second hypothesis called the issue public hypothesis predicts that voters seek information on policy issues of great personal importance. In the presidential election context of 2000, the researchers found that Republicans preferred to access information about Republican candidate George W. Bush, but Democrats failed to prefer information about Democratic candidate Al Gore. However, there was strong evidence for the issue public hypothesis. This

finding ties in with a more pragmatic theory of news selection. Uses and gratification theories suggest that an individual follows particular news stories and political messaging that will prove useful or gratifying to the individual (Garramone, 1985; see also Graber, 2006; Sears and Freedman, 1967).

The impact of mass media on individuals may also be lessened by the lack of interest and attention, or for that matter, the accumulation of political knowledge. Beginning with Converse (1964), scholars have recognized that the inattentive and uninterested comprise a significant portion of the American electorate, a finding that is replicated to a somewhat lesser degrees in election studies in other nations. John Zaller (1992), while constructing a general theory of opinion change and mass communication, offers two additional assertions. First, the likelihood of receiving a political message depends on an individual's general information about politics. People with greater levels of information are more likely to expose themselves to political communication and to understand the messages and information received. The second observation is that people resist political messages that are inconsistent with their political predispositions as long as they have context information sufficient to recognize the inconsistencies. The greater an individual's attentiveness to public affairs coverage in the mass media, the greater the likelihood that the individual will resist political messages. Elisabeth Noelle-Neumann (1974) proposed another effect on public opinion resulting from the mass dissemination of opinion. The spiral of silence theory suggests that individuals who perceive their opinions in the minority will be pressured to remain silent or to express a majority opinion. Noelle-Neumann emphasized that individuals find it more important to avoid isolating themselves socially than they think it is to express oneself. She also recognized a dynamic element in the spiral of silence; if an individual perceives his or her viewpoints not just as dominant, but also to be gaining acceptance, the individual will be willing to express those opinions publicly. Noelle-Neumann argued that when mass media disseminates opinion throughout the society, minority viewpoints are increasingly excluded and the majority opinion acquires increasing attention and legitimacy. The mass media's role in this spiral can be extended a little farther: the mass media disseminates the most common perspectives in order to appeal to consumers and sell its products, legitimizing the majority opinion, and providing an environment in which holders of minority opinions perceive a hostile environment for expressing their views. For more than 20 years following its publication, the spiral of silence was considered one of the most influential theories of public opinion formation, but testing of the theory and its hypotheses has not focused on the dissemination of dominant opinions by the mass media. A review of more than 15 published studies based on the theory provided inconclusive evidence of the effect of majority opinions in survey-based studies (Glynn et al., 1997), prompting a recommendation that experimental designs might provide better tests of the theory.

Media-Centered Political Behavior

Much of the research on politics and mass media reflects a concern for the mass media's roles. Traditional interpretations of the mass media suggest three main roles in public and political affairs: the collection of and dissemination of news and information about public affairs, which may include analysis of that information and the setting of the news in context; the provision of a forum in which to debate public affairs and political choices; and the provision of a watchdog or whistleblower function to alert citizens to the failings of their government and political institutions. Critiques of the former role often function on normative concerns over whether news organizations and reporters can maintain objectivity and balance in the presentation of news, but this concern has faded with the creation of organizations that emphasize niche audience in a limited segment of the political spectrum rather than the general audience. The plethora of news media outlets that emerged with the development of cable and satellite TV providers and Internet news operations has greatly enhanced opportunities for the mass media to serve as a forum for public debate, although that debate is sometimes one sided within a single news entity. (For example, in the United States, both Fox News and MSNBC reflect discernible bias in their presentation of news and commentary. In the United States and other countries, public television channels often attempt to maintain a more balanced alternative to private news operations.)

A larger question is the extent to which mass media determine the content of the public affairs debate. Bernard Cohen's study of the press and U.S. foreign policy (1963) was among the first to recognize that where the press might fail to persuade people about what to think, the mass media did indeed tell its readers what to think about. Cohen noted that editors often believed that their publications were simply serving the preferences of an attentive, expert audience, which limited the scope of their conclusions. McCombs and Shaw (1972) were not so constrained in correlating local and national news coverage with the problems that uncommitted voters around Chapel Hill, N.C., identified as needing attention. Although the study's strong correlations seemed to establish the importance of mass media to establishing the political agenda, subsequent research has weakened the findings, showing that context, personal experiences, levels of political discussion, and television news watching (Iyengar and Kinder, 1987), all impact the ability of the mass media to set political agendas for individuals. But so do self-interest, group membership, and ideology. The agenda-setting function for mass media is enhanced by gate-keeping behavior by editors and news directors, who determine what news is of interest to their subscribers, viewers, and other audiences.

Mass media also exercise a form of personalized agenda setting in elections. Primary elections eliminate the partisan cues that many voters use as judgmental shortcuts (i.e., heuristics) in general elections, hence it falls to the mass media to define the roles for particular offices and cast candidates in those roles (Graber, 2006). The mass media also define the winners and losers of election contests in terms of pre-election expectations (Bartels, 1985). Thus, a winning candidate in a primary election who fails to achieve victory by an expected large margin may be perceived to have 'lost' the contest. Similarly, a second candidate who lost the election but performed better than predicted may be perceived as a 'winner.' Both these approached to news coverage comport with the preference of the news media to

cover dramatic horse-race aspects of elections and image-based events rather than complex and visually unappealing policy debates and performance evaluations that motivate the choices of many voters.

The mass media also act on public perceptions and evaluations of issues and candidates through priming. Priming occurs when the mass media focus on a limited set of issues, policies, and characteristics, establishing a framework of judgmental standards for individuals. If newscasts and news articles focus on national defense issues or a crisis in the national economy, an evaluative framework is provided for viewers and readers (Iyengar and Kinder, 1987). The flip side of the priming coin is the selection made by mass media to frame particular issues in a particular perspective. When small numbers of broadcast news operations dominate national news dissemination, framing by one news entity often coincides with that of the others, as each media operation competes to attract a larger share of the same mass audience. With the emergence of lucrative niche news operations and the explosion of expert blogs, there is no lack of frames from which news consumers may choose.

Of some concern to partisans and researchers alike is whether various media outlets derive a particular slant or bias in their presentation of news. For most of the twentieth century, the most credible news organizations in the United States and around the world were regarded as having sublimated the political preferences of the editors, publishers, and owners in their news columns to the reportorial standards of objectivity, fairness, and balance. While editorial pages framed content on the editorial and opinion pages with the particular interests of editors, publishers and owners, reporters, and news editors were expected to maintain a relatively objective and balanced approach to news despite their individual political preferences. Prior to the emergence in the 1990s of the punditry model of news shows on cable television, most print and broadcast news operations maintained strict separation of the commentary and news functions.

Groseclose and Milyo (2005) recognized this division in generating a measure of news bias that focuses on the reporting of news. Excluding editorial page, opinion page, and external commentary from their study, the researchers found a liberal bias in the news columns of 20 national news organizations, including some that are generally regarded as conservative in their presentations. Media bias was defined as the disconnect between the measured political ideologies of average American voters and the reported news content. These ideological differences were measured comparatively by analyzing the citations of advocacy organizations and think tanks used by reporters and members of Congress. The researchers used standard ideological ratings of legislators to define the ideologies of advocacy organizations and think tanks, then extrapolated the ideology of the sources to generate ideological scores for the news organizations that used them. The central ideology of the voting public was extrapolated as a function of the political ideology of their representatives. Groseclose (2012) later expanded the initial study in a normative book, *Left Turn*, estimating that biased reporting altered the political perceptions of American voters with the effect of adding 8 to 10 percentage points to Democratic vote share in a typical election.

Significant scholarly response to Groseclose's book prompted a symposium discussion of his work in an American Political Science Association journal (Nyhan et al., 2012). Much of the commentary praised the creative attempt to model bias and internal validity of Groseclose's approach, but questioned his foundational assumptions and the failure of the theoretical models and counterfactuals to capture political reality. In addition to these valid critiques, the book failed to consider the substantial differences in the purposes of legislators and journalists (policy advocacy as opposed to informing the public and increasing readership) and a demonstrated profound misunderstanding of how reporters gather and use expert sources on deadline (i.e., there is satisficing behavior at work and sources with effective media response teams will be contacted).

Gentzkow and Shapiro (2010) also examined the concept of media slant among American newspapers and, like Groseclose and Milyo, found evidence of bias in news organizations. But Gentzkow and Shapiro concluded that the viewpoints of the newspapers reflected less of the particular ideological bias of the newspaper owners than an attempt to satisfy what was perceived as the publication's audience. A publication's slant was the result of the desire to promote a reputation of accuracy and sustaining existing readership while drawing in new readers. Thus, slant was more a matter of economic incentive than an effort to promote particular parties or ideologies.

Studies of media bias and coverage in the twenty-first century are based on text analytics, the now automated practice of analyzing the text of news broadcasts and publications to determine what is being discussed, by whom, for whom, and with what evidence. Analyzing text is not new, but what had been a slow process involving graduate student and volunteer coders volunteers is now the province of automated algorithm-based scanning of text, sound bites, and video clips. These algorithm-based programs were initially conceived as a tool for marketing and business intelligence, but their design has involved several top quantitative social scientists, including Harvard's Gary King. In addition to counting hits of words and phrases, the new programs are able to evaluate context and meaning to generate relevant data. The new content-based data may lead to substantial revisions of communications and political theories in the next decades.

Changes in Mass Media Ownership

Since the 1970s, changes in the commercial structures of news organizations and their parent corporations have led to vertically and horizontally integrated media corporations in which unprofitable news operations are tolerated for their contributions to public service and community involvement. Moving from a model of individual or family ownership of mass media to a centralized corporate conglomerate model has subjected many news organizations to corporate demands that they become profit centers, a goal that is often hard to achieve. For most news organizations, advertising dollars accumulated in the entertainment portfolio – not the news and public affairs portfolio – and news operations were often subsidized by income in other divisions of the media corporation. International affairs journalism, traditionally conducted by

newspapers and broadcast news organizations by posting a series of correspondents and stringers around the world, soon faced drastic cuts as rising operating costs of newsprint and nonlocal staff combined with falling local advertising revenues, which were now going to television stations or to Internet advertising. Political advertising was no exception, with expensive broadcast advertising being replaced by cheaper, narrowly targeted Internet and cable advertisements (*see* Political Advertising).

But the late twentieth century also saw the emergence of a new model of profitable media corporation that has the potential to affect political news. Where the standard mass media strategy was to appeal to all elements of the audience in offering political news, Rupert Murdoch's News Corporation and Fox News broadcast and cable news operations pioneered the idea that niche journalism – a punditry-based approach to television news that appealed to a particular right-wing point of view – could be profitable. In the twenty-first century, the Fox News model was proving to be more profitable than news networks that remained focused on the general audience.

Impacts of Technology: Television and Cable News

Foundational theories on the relationships between mass media and politics were laid down in the 1940s and 1950s, but the explosion of communication technologies from the 1980s into the early twenty-first century invites revision of existing theory in a more complex and immediate communications environment. From 1960 on, the emergence of broadcast and cable television, the creation of the Internet, and cell phone and other wireless technologies have prompted reconsideration of theories about how the mass media influences politics.

With the ascendency of television news after 1960 as the main source for many citizens in industrialized democracies, the role of the mass media in political systems changed. No longer were journalists hunter gatherers of news, foraging among party and executive branch leaders, legislators, lobbyists, bureaucrats, campaign consultants, and interest groups. Television news operations became co-producers of political news (Gurevitch et al., 2009). Television moved reporters from observers of the political environment to constructors of a new political reality. The visual nature of the medium also transformed the nature of electoral campaigns from a primary focus on complex and difficult issue debates and incumbent performance evaluations to a simple emphasis on the construction of candidate images. Image and symbolism, always an element of campaign flyers and mailers, achieved an immediacy with the live and video coverage of campaign events and photo opportunities. Many candidates and campaigns, understanding the visual limits of lengthy discussions of policy choices, opted instead for image over substance. If a picture is worth a thousand words, an image is equally valuable because the opposition cannot hold a debate with it. One example of this behavior is the scripting of American political conventions: mobilizing the party faithful and constructing a party platform is no longer the aim. Rather, the convention is constructed as an opportunity to garner free and unanswered media coverage that promotes candidate and party image, including the presentations of sometimes false images of the diversity of the party.

The emergence of broadcast news reduced selective exposure to party propaganda in both parliamentary and presidential democracies, established nonpartisan norms of news presentation, and enlarged the audience for political news (Blumler and Kavanagh, 1999). But a 'third age' of mass media was marked by the increasing popularity of cable television, which avoided the limited broadcast bandwidth problem and allowed for expanded content and channels. Channel multiplication led to audience fragmentation: no longer did the bulk of national populations share a common information stream. Much of the news audience for television in the days of the three major channels was inadvertent, composed of audiences waiting for a particular sitcom or entertainment show (Bennett and Iyengar, 2008). With the multiplication of available channels and the presence of specialized news channels, the inadvertent audience ceased to exist. Rather, individual viewers in the age of cable news were empowered to select news that fit their particular partisan or ideological biases. The creation of an expanded Internet compounded the abundance of political news and the sources from which that news could be gleaned.

The new communications technologies also altered the relationship between parties and candidates. For one thing, the emergence in the United States of the concept of the permanent campaign – i.e., politics is about individuals and parties taking and holding power, not about effective governance of the community – stresses the importance of partisan action and reaction, necessitating that parties and candidates keep a weather eye on the news media and how to obtain constant coverage of party and candidate positions. The legislative or management record of parties and candidates matters less than the record of media-disseminated statements in support of party or ideology. At the same time, the computer and new media technologies have altered traditional roles of the party as providers of communications expertise, voter information, and campaign logistics. This is most prevalent in presidential systems like the United States, where candidates are often chosen in party primaries and may propose platforms that are at odds with the party on certain items. The availability of computerized voter and primary election records allows candidates and officeholders to purchase such information cheaply and directly from the government, and selectively target voters, all without the help of the party apparatus. A well-funded candidate may speak directly to voters before primaries through carefully targeted television, direct mail, and email campaigns, all without the constraint of their party. Parties have little choice but to fall in behind the positions of their leading candidates.

Brave New World: Politics and the Internet

The development of Internet from a network of research institutions to a ubiquitous worldwide web used by citizens around the world prompted even more change for politicians. Citizens gained news opportunities to search for and immediately access news from a vast range of sources, act as citizen watchdogs over the excesses of corporations, governments, and international organizations, participate in political discussions and organize around political interests. But there is a downside: the unregulated diversity of political voices on the Internet

allows for wide dissemination of extremist views and promotes the ability of extremists to link with like-minded individuals (Mutz and Young, 2011). The Internet offered candidates yet another channel of communications, and one that could be used not just to target supporting voters cheaply. The fundraising successes of Howard Dean's, 2004 campaign suggested to candidates and political parties that the Internet could also be a powerful tool for mobilizing small contributors behind candidates, and within 4 years the Obama presidential campaign was campaigning and fundraising with online technologies coordinated with traditional campaign functions. The Obama campaign may be the exemplar for future campaigns in developed democracies, with campaigns utilizing marketing and computer-assisted marketing analysis to identify target audience, followed by a multichannel delivery of messages to the targeted audiences. The need for communications-savvy staff already has led campaigns to professionalize by hiring partisan consultants to direct campaign communications across a multitude of channels. Government agencies and officeholders soon followed the campaigns into upgrading the communications function and hiring a professional communications staff.

The Internet offers several challenges for research on dissemination of political news and commentary. One pertinent question is whether the new media – cable news, talk radio, and blogs – have focused on their niche audiences to the exclusion of alternative viewpoints and balance. Baum and Groeling (2008) found that the new media provided more partisan filtering of the news than news services like Reuters and The Associated Press.

A key question is whether the expanding availability of news sources and political commentary on the Internet undermines the socializing role of the traditional mass media, a question that is linked to selective exposure in a high-choice media environment. Although most Internet public affairs news sites have small audiences compared to traditional print, broadcast, and cable news organizations, many of which now have a presence on the Internet, the focus on these fragmented smaller audiences raises concerns that there is less common perspective on public affairs than in the past (Putnam, 2000, see also Norris, 2001). In the United States, this translates to concern whether the fragmented audience is composed of large numbers of individual who selectively expose themselves to news sources that reinforce their partisan and ideological preferences. Such behavior could give the mass media a role in explaining why the American electorate is becoming more polarized, an assertion that is itself hotly contested.

Much has also been made of the Internet as a new political tool for mobilizing a sense of freedom and democracy within authoritarian states. The Arab Spring uprisings of 2011 provided some grist for the arguments that the Internet provided the technology for breaking the hold of authoritarian regimes, which largely control the national and local mass media as a first priority. In Tunisia and Egypt, the communication costs of collective protests actions was largely reduced by the use of Facebook and Twitter to mobilize protesters and communicate among activists. There is also some evidence that the preference falsification that kept citizens living under authoritarian regimes from realizing the extent of opposition to the regime was undermined by exchanges on social media sites such as Facebook (Lynch, 2011).

Thinking Ahead

Among the normative questions that remain unanswered for all democracies is how well the mass media serve the democratic roles of providing information, forums for discussions, and a watchdog on the excesses of government corruption and secrecy. Among the democracies, the general answer is that the mass media, government, parties, and interest groups provide an imperfect market for ideas on how to govern society. One strategy for improving that performance is to provide enhanced openness and transparency for government records and governmental decision making. Another line of attack by critics of the mass media is to call for new regulations that will at least preserve access to public affairs programming and news in mass media where economic costs or limited bandwidth results in less coverage of public affairs, and may have dire consequences for public support of governmental systems and governments.

Although much has been made of the Americanization of campaigns and political communication through the use of American political advertising and marketing techniques, there is a substantial question of how well the theoretical pillars apply across a developing world comprising diverse political cultures and systems. The overlap of such communication strategies in different cultures is likely to produce a variety of results.

Mass Media and Sports

David Rowe, Institute for Culture and Society, University of Western Sydney, Penrith, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Mass media and sports have become increasingly entwined in modernity, now forming what can be called the media sports cultural complex. While television, the most powerful contemporary medium, has made sports increasingly accessible to audiences, there is scholarly concern that it now dominates and even degrades sports. Political economic analysis has, therefore, been an influential approach in this scholarly field, but it is also important to engage with the dimensions of sports that recognize how it works in diverse ways as culture. Therefore, analysis of media sports meanings, ideologies, and uses is important in an increasingly globalized and digitized environment.

From the vantage point of the twenty-first century, it is increasingly difficult to conceive of professional sports existing independently of the mass media, and of the mass media continuing to operate without a substantial infusion of sports content. Once social and cultural institutions that were not only autonomous but also competitive and mutually suspicious, mass media and sports in modernity have intermeshed so extensively as to now constitute what can be described as the 'media sports cultural complex' (Rowe, 2004). This concept builds on earlier conceptions of institutional and industrial interpenetration of mass media and sports to embrace the much greater, multidirectional flow of mediated sports texts, genres, practices and meanings in local, national, transnational, and global contexts.

There are two enduring, principal problematics addressed by social and behavioral scientists regarding the relationship between mass media and sports. The first derives from significant concern about the power of the media over other institutions, including through the process of mediatization by which disparate sociocultural phenomena are not just represented by the media but changed, and even transformed, by media representation. In the case of sports, which has a strong historical thread of romanticism as an autonomous domain beyond everyday politics and economics, there is specific analytical anxiety that the mass media – especially television, since the second half of the twentieth century – has become dominant in sports and consequently to have degraded it. The second, related principal problematic concerns the mediated politics of sport and, specifically, how the media can, in ideological terms, harness sports to particular, often negative social ends. Thus, media sports are often analyzed and critiqued as complicit in the dissemination and reproduction of social class inequality, sexism, racism, xenophobia, ethnocentrism, homophobia, and so on. A long-standing area of concern is that the media offer a bread and circuses distraction of whole populations, thereby obstructing challenges to prevailing structures of power. Such concerns persist despite major changes to the field of mass media and sports, including technological changes that may be said to have empowered previously passive media sport consumers. In addressing these issues from a social and behavioral sciences perspective, this article begins with a sociohistorical explanation of the convergence of institutions of media and sports, and elaborates on the analytical utility of the concept of the media sports cultural complex.

The Rise of the Media Sports Cultural Complex

The institutions of the mass media and sports developed in parallel as a consequence of modernity's transformative impact on both the reach and speed of communication, and the prominence and organization of physical play. The mass media emerged, in both public (state) and private (commercial) manifestations, as the key institutionalized communicator of political discourse, bearer of news, provider of entertainment, and vector of 'promotional' messages of various kinds. As the commercial mass media developed, so did advertising as a major income stream that sustained the burgeoning media apparatus. For example, the economics of commercial free-to-air television and radio were, from the first, dependent on their capacity to capture large, reliable audiences for exposure to advertised products and services. Broadcast ratings, as a measure of audience size and penetration, could be converted into measurable advertising and promotional value for which the media, as both audience generator and gatekeeper, would be well compensated by commercial entities. Technological innovations, such as more efficient printing presses and satellite signal transmission, created an ever-growing media space where systematically stimulated audience demand required enhanced media supply. The proliferation of media channels made 'premium' content even more valuable, and hence created greater pressure to provide compelling news and popular entertainment in an information and image market that was becoming more complex and competitive. Crucially, sports was well suited to fulfilling this task.

While physical play has been a feature of all known societies for millennia, the specific social institution of sports – with its binding rules, carefully calculated scoring, regular competitive events, industrial provision of space, apparel and equipment, and large-scale operation at national and international levels – is a phenomenon that only began to take full shape in the nineteenth century. Sports emerged as an important collective manifestation of popular leisure

and pleasure (Boyle and Haynes, 2009), developing (first in Britain, which, not coincidentally, was also the pioneering industrial and capitalist power) from intermittent forms of 'folk' physical play on feast days and holidays into codified disciplines in which participants were either lovers of the game (amateurs) or skillful paid-performers entertaining paying spectators (professionals). As sports became more commercialized and, crucially, mediatized, professional sports progressively overshadowed its amateur forms. As the process advanced, the British imprint on sports weakened in the face of the American influence on sports media (especially television), promotion and marketing. It was in the United States that the commercial potential of sports as a mediated phenomenon was most comprehensively grasped.

Sports began to commend itself to the media as an ideal source of content that would draw in large audience cohorts, able to flow across the entire spectrum of news, entertainment, and public affairs in a manner that has now made 'mediasport' pervasive in contemporary culture (Wenner, 1998). The immediacy of sports, involving the unscripted unfolding of events in real time, invited reportage (news) while, at the same time, being captured and packaged by the media (entertainment) as content for display. This content produced more news (in both hard and soft forms) flowing from this content display which, in turn, stimulated more coverage and interest in future-mediated sport content, and so on. It is here, at the intersection of the media's need for content and sports' desire for profile that the genesis of the media sports cultural complex can be found.

It seems curious given the intensive entanglement of mass media and sports that they were initially, mutually cautious in establishing a framework for cooperation. The electronic media, in particular, were initially skeptical that sports could sustain its audience appeal after its novelty value wore off, while various sports organizations were concerned that armchair listening and viewing would reduce paid attendance at enclosed sporting events and so undermine their economic sustainability. As this relationship came to be viewed as more symbiosis than competition, the pivotal bargain struck over broadcast rights – as the single largest element of the sports economy – has both endured and matured. Sports, then, while a major staple subject of the press, radio, and the Internet, has formed its closest and most lucrative alliance to date with television. This article, as a consequence, pays particular attention to the television–sports nexus, which has had a profound impact on the economics, politics, and social dynamics of contemporary culture on an increasingly global scale (Billings, 2011). Sports is not only a prominent genre (or set of genres) of media content, but has much more extensive sociocultural resonance (as discussed later).

In general terms, the two principal forces behind the growth of media sports have been nation building and market development, with the balance and rate of development varying according to social, historical, and spatial context. In Britain, for example, a strong impulse to nurture national culture has been evident through the state-fostered pioneering radio and television representation of great national sports events, like the Grand National and Derby horse races and the soccer FA Cup Final, by the public British Broadcasting Corporation. These were prime instances of the mass media communicating the nation to itself, and seeking to convey a sense of a seamless notion of British (especially English) identity (Whannel, 1992). Contrastingly, in the United States, a much larger, newer nation in which the public organization of broadcasting was subordinated to commercial impulses, the market potential of mass media sports was, in the first instance, more speedily realized. More recently, as mediated sports has become a progressively global phenomenon (Rowe, 2011), sociohistorical differences have produced many local variations in other continents and nations, although still within limits imposed by its formative agents in the Anglophone West. A key reason for sports' rapid global diffusion is its extraordinary capacity to appear in many forms across a variety of national and international contexts, simultaneously reproducing, adapting, reshaping, and extending the media sports cultural complex.

Media Sports Forms, Genres, and Texts

Sports is especially serviceable to the mass media because of its extraordinary adaptability to a range of media formats, including live broadcast action, dramatic still photography, short and lengthy print stories and, increasingly, Web-based exchanges between journalists and fans. Broad developments in media technologies, genres, organizations, and audiences have molded sports' media representation and use, but it has also been influential in shaping the media landscape in nonsports areas. The initial coverage of sports in the mass media – which can be traced back to the early eighteenth century – was print based. In the absence of instantaneous electronic sports news production, the prime purpose of the mass media was to report significant sports events and to record their outcomes in a manner that would attract and sustain substantial readerships. With sports developing as a popular pursuit in the late nineteenth century, sports reports became more elaborate, with detailed descriptions of play and the poetic elaboration of event atmosphere. Prominent organized sports was routinely discussed in the media, and sports events were treated prospectively in stirring anticipation of athletic encounters, which were then minutely analyzed and subjected to comparative quantitative measures of scores and performance patterns. By this means, sports was both advertised in the media and, in drawing audiences to its coverage, used as a vehicle for advertising other products. Sports illustrations, action and portrait photography, and sports-infused advertisements (including those using prominent sports people to endorse products) helped to develop the visual aesthetics of media sports, which emphasized the capture of dramatic action in the frozen moment of the still photograph (later made more vibrant by the replacement of black-and-white by color), as well the noble, perhaps poignant athlete portrait that drew on and reinforced sports' heroic mythology and iconography.

The coming of the electronic media brought unprecedented potential for instantaneous media sports coverage that even accelerated print production schedules could not match. From

the 1920s onward, radio delivered real-time coverage and ambient sounds to growing audiences for soccer, boxing, baseball, cricket, and other sports, creating a new cultural practice of home-based and then mobile (including motor car-based) radio listening to live sports. Descriptive and analytical summary, combined with actual recorded and even synthesized sound, gave some sense of having been there for distant, dispersed but interested sports followers. But it was broadcast television that had the unrivaled capacity to simulate plausibly the experience of physically attending sports contests. Although at its most experientially intense and economically valuable in live broadcast form, sports television could also, through delayed telecasts, replays, highlights, and so on, overcome some of the limitations of temporality by evoking a sense of simultaneity and/or drama long after sports contests had concluded in real time.

As television technology developed, the use of multiple cameras, instant replays, slow (and, later, super slow) motion, split screening, data call-up, and other innovations made the remote-viewing experience in some regards superior to that of actual attendance at the event (leading to the rather paradoxical insertion of large television screens into sports stadia). It is for this reason that live TV is the most prized and valuable form of mass media sports. While orthodox broadcast sports television is currently dominant, live action is increasingly moving onto other screens – notably computers and mobile devices – while broadcast and Web-based technologies are also converging in ways that are transforming how, where, and in what technological–textual combination mediated sports is experienced (Hutchins and Rowe, 2012).

Live TV sports is a perishable form, but its media life can be preserved and extended by acting as a reference point for many other types of programing, including sports magazine shows; previews, *postmortems*, and retrospectives; quiz and chat programs; and documentaries and sport-based dramas supplementing regular sports news bulletins and updates. Confronted by television's capacity to create many different types of sports text, the print media adapted by utilizing the reflective space provided by the written form to expand the sports pages in newspapers (often including large daily sports supplements) and to produce many general (the best known of which is *Sports Illustrated*) and specialist (such as *Baseball Digest* and *Hoop*) sports magazines, all of which are accompanied by sports photography (sometimes in the form of sports photo essays). At the same time, sports organizations and celebrities are covered extensively in general news, not least by means of proliferating sports celebrity scandals and the more routine use of the gossip column. When the many novels and films that deal centrally with sports are included, as well as its key role in the promotion, advertising, and endorsement of products and services from soft drink and leisure wear to life insurance and fitness programs, the degree to which mass media sports has become both ubiquitous and multifunctional can be fully appreciated. Each new media technological innovation has generated novel possibilities for sports, such as multimedia Web sites, sports video games such as *Madden NFL* and *Tiger Woods PGA Tour*, and more physically interactive sports simulation games such as *Wii*.

Indeed, the imprint of sports can be seen in the emphasis on liveness, competition, and partisanship in so-called reality television, and in other genres that rely on uncertainty of outcome and audience (both copresent and distant) involvement. This sportslike quality can be found in popular, though disparate television programs like *Survivor*, *Big Brother*, *The Biggest Loser*, *Beat the Star*, *The Chase*, *The Whole 19 Yards*, *Wipeout*, and *Iron Chef*. Each of these programs, in their different ways, contains elements that can be found in mediated sports contests, thereby suggesting that contemporary popular culture is becoming to a degree 'sportified' by drawing on the habitual (and so largely unconscious) cueing of audience expectations of contest, spectacle and, crucially, a quantifiable result that in most cases determines unambiguous winners and losers. The success of the mass media in insinuating sports into the fabric of everyday sociocultural life – even for those who are hostile or indifferent to it – has raised significant questions about its social and ideological ramifications, and provoked keen debate and substantial scholarship (for example, Raney and Bryant, 2006) about what it means to live in societies where sports has passed, in barely two centuries, from rough play in rural communities to rationalized, highly capitalized, and globalized cultural spectacle.

Analytical Approaches to Mass Media and Sports

Until comparatively recently, social and behavioral scientists have tended to neglect mass media and sports as a suitable area for systematic research and scholarship, preferring to concentrate on the formal politics of the news media or the corporeal dimensions of sports. Where sports was addressed as parts of mediated entertainment, it was usually not given the close analytical attention of, for example, film and television drama and documentary, but treated more generically as one form of commercialized popular culture merging with another. However, as sports became increasingly cultural visible and economically integral to the media, scholars in traditional disciplines (such as sociology, psychology, economics, and philosophy) and new interdisciplinary areas (like media studies, cultural studies, sport studies, and leisure studies) began to engage more intensively with it from the mid-1980s onward. The field has been shaped by three principal concerns: How is media sports produced, what does media sports mean, and how do audiences receive and use media sports? For example, great global and national-mediated festivals of sports, with their reliance on a combination of deep belief and spectacular ritual, began to be seen as a powerful form of secular religion under late modernity or as offering a particularly powerful symbolic narrative of common identities and expressions of difference. However, as noted, a more powerful initial strand in mass media and sports research, drawing in part on the Corinthian ideal of noble amateur sport or on its original status as uncommodified folk physical play, involved a critique that commerce, especially in its embrace of television, has degraded, colonized and corrupted sports, and exploited its audiences.

Although there have been various changes to the mass media–sports relationship over the last 30 years – for example, the increasing involvement of umbrella sports organizations and clubs in producing their own media content – this political economic perspective critiquing corporate media power

remains pivotal in much media sports social and behavioral science. Particular emphasis is placed on the media's capacity to modify sports to make it more suitable for requirements such as advertising breaks and audience retention. Thus, the introduction of tie-breaks in tennis; shorter cricket contests like one-day and Twenty20 matches; longer time-outs and the shot clock in basketball; the designated hitter in baseball; penalty shoot-outs in soccer; more breaks for commercials in gridiron; minimal scrum rules in rugby league; and the speeding up of rucks and mauls in rugby union can be attributed wholly or partially to the drive to make sports more telegenic and/or commercially valuable. The political economic critique of mass media sports has, therefore, emphasized the intensification of the media–sports nexus and the large-scale growth of the media sports cultural complex. The sale of live sports broadcast and other media rights, and the development of global media sports corporations, have focused scholarly attention on the conditions of production of mass media sports.

Live TV sports is able to bring global audiences simultaneously to the screen in massive numbers. For example, the estimated cumulative television audience for the 17 days of the 2008 Beijing Olympics was 4.7 billion viewers, exceeding those of the Athens 2004 (3.9 billion) and Sydney 2000 (3.1 billion) Games. Although such numbers are often exaggerated and misused for promotional and commercial purposes – for example, the claim that 70% of the world's population watched some of the Beijing Olympics does not take into account repeat rather than unique viewing – they nonetheless represent impressive evidence that advertisers and sponsors can find enormous audiences through sports. Thus, they are willing to pay for the privilege to broadcast sports and be conspicuously displayed at mediated sports events. Although television is still the dominant sports medium in the second decade of the twenty-first century, technological development in the media field has produced important audiences involving other platforms and devices. For example, at the 2010 FIFA (Fédération Internationale de Football Association) World Cup in South Africa, over 220 000 people followed the official body's Twitter feed, while its Web site FIFA.com attracted over 250 million visits, including 410 million page views in a single day. As such media sports viewing increases, so does the cost of acquiring its rights, with the US TV broadcast rights for the summer Olympics paid by the National Broadcasting Company (NBC) network rising from US$72 million in 1980 (before the landmark 1984 Los Angeles Games, which in their then-unprecedented commitment to commercialism were characterized as The Hamburger Olympics) to US$894 million for the 2008 Olympics. Here, the professionalization of the Olympics, which once prized its amateurism, is starkly revealed, with its governing body, the International Olympic Committee (IOC), developing and assiduously protecting the global commercial value of its sporting product. Such commodification permeating both organizations and athletes, from a critical political economic perspective, increasingly parallels the culture of commercial media corporations whose aggressive competition for sports rights is matched only by their defense of their acquired intellectual property in the form of exclusive mediated sports.

Media sports political economists, therefore, monitor closely the power of media (and, increasingly following the rise of the Internet, telecommunications companies, and Internet service providers) corporations who bring sports spectacles to a substantial proportion of the world's citizenry. For example, NBC (jointly owned by Comcast and General Electric) is in competition for prime TV sports assets with other corporations such as the 21st Century Fox-owned FOX network (controlled by the world's most powerful and, perhaps, notorious contemporary media sports proprietor, Rupert Murdoch) and the Entertainment and Sports Programing Network, which is owned by the Walt Disney Company and the Hearst Corporation. This competition for mediated sports content goes far beyond mega sports spectacles like the Olympics and the FIFA World Cup. Large local, regional, national, and (with the growth of satellite pay TV and online sports) inter/transnational audiences can be attracted by regular, long-form sports competitions within single countries. Hence, for example, the United States' most powerful sports league, the National Football League (NFL), received US$20.4 billion for free-to-air and pay television rights in its most recent contract, with the value of the 2014–22 broadcast rights substantially higher at almost $40 billion. The not-inconsiderable value of nonbroadcast rights, as well as of the broadcasts of the League's own NFL Network, indicates the contemporary capacity to convert premium sports into high-level media capital.

Sports is crucial to free-to-air television in generating advertising revenue, while for pay television it is the most important content generator of subscriptions, even overshadowing major, first-run films (which lack the immediacy of real-time mediated sports). Of particular concern to political economists of sports is the question of access to mass media sports for the citizenry in general. In many countries (the USA being a signal exception), sports was first shown, and for many years dominated by, public service television as a key aspect of nation building through common cultural ritual. Although commercial free-to-air television subsequently supplemented and, frequently, came to displace and dominate public sports television, its relatively open platform ensured exposure to most sports events of national importance and cultural significance, although this arrangement also required often-resented exposure to advertising messages and hyped up commentary and presentation. When subscription television began to outbid both public and commercial free-to-air broadcasters for sports rights, a barrier to access was immediately introduced on the basis of socio-economic class/income. In countries such as the UK, pay television from the early 1990s onward emerged as the most powerful media force in sports. Indeed, it was exclusive sports rights that were crucial to its establishment in the UK, with the Rupert Murdoch-controlled BSkyB satellite service's securing of the broadcast rights to English Premier League (EPL) soccer in 1992 saving the nascent subscription service, turning a struggling pay television company into the most profitable of all British media inside a decade.

But the siphoning of the best content in Britain's most popular sport from free-to-air television created some public and government resistance, and the analytical interest of media sports scholars, with anxiety about the next step in the direction of commodity logic – the ownership and control of leading sports clubs by the media companies that broadcast

them – rejected there at the advent of the twenty-first century. Although the convergence of sports, business and media interests is common in other parts of the world – for example, ownership of European soccer teams A.C. Milan and Paris St Germain by the (former Italian Prime Minister) Silvio Berlusconi-controlled Mediaset and Canal Plus respectively, and the (now relinquished) ownership of the Los Angeles Dodgers baseball team by (the then) News Corporation – there was uneasiness in Britain about the same vested interest being on both sides of the bargaining table. Thus, a 1999 takeover bid by News Corporation of one of the world's most famous sports brands, Manchester United Football Club, was blocked on grounds of both diminishing competition in the broadcast market and with regard to a wider public interest test of exacerbating inequalities between association football clubs in Britain. The EPL's provision of highly skewed broadcast rights revenues via BSkyB to only 20 out of 92 professional football clubs has created an unprecedented economic divide within British football. This belated social-democratic resistance to the extension of the power of media and of other commercial corporations over sports was recognition by the state of the groundswell of anticoncentration sentiment among grassroots sports fans and their representative bodies (as well as a response to pressure by commercial competitors of BSkyB).

In this instance, the economic power of media capital, the responsibilities of the state, and the civil societal place of sports are simultaneously the concern of the approach to mass media and sports that emphasizes sociopolitical conflicts caused by the intensification of commodity logic within the media sports cultural complex. While this inquiry sprang first within national media sport systems, that framework is increasingly inadequate given the development of a transnational/global mediated sports regime. There is increasing saturation of mature Western media sports markets, leading to the globalization of major sports clubs brands in soccer, basketball, baseball, gridiron, and so on, and especially targeting the fastest growing economies of the populous Asia Pacific region (Rowe, 2011). Here, the image appeal of astutely marketed Western sports often overshadows local sports competitions in a manner that recalls long-standing analyses of media and cultural imperialism. These developments, alongside the growth of mass media and sports research and scholarship in non-Western contexts, have begun to break down the Western dominance of the academic field in a manner mirroring that of the media sports field itself. Social and behavioral sciences work on mass media and sports is required to be less-nationally insular, and the international field is gradually becoming less-fixated on the West, and more open to analytical interventions from places where the media sports landscape is rather different (Bernstein and Blain, 2003).

Despite the unquestionable contribution of the political economic approach to the social analysis of mass media and sports, it is not equipped comprehensively to explain the sociocultural processes by which some forms of mediated sports take hold in particular contexts, while others do not, nor does it usually provide the necessarily detailed interpretive analysis of the meanings and ideologies of mediated sports texts and their interaction with diverse audience cohorts. In short, the ways in which mass media sports works as culture and connects with a range of aspects of sociality needs to be understood through a wider research agenda and other methods. In addressing these questions and shifting focus from the more orthodox economic aspects of the production and consumption of mass media sports, culturalist approaches (incorporating both Cultural Sociology and Cultural Studies) have been influential in attending to media sports as a significant aspect of the fabric and politics of everyday life (Horne, 2006). In seeking to divine the meanings and uses of media sports, the identities it helps to construct and reinforce, and the social fault lines and points of resistance and incorporation that it lays bare, this broad approach has not so much sought to repudiate political economic approaches as to deter abstract, one-dimensional conceptions of media sports markets, producer and consumers.

Culturalist analyses of media sports (through interdisciplinary combinations of elements of ethnography, sociolinguistics, semiotics, and so on) seek to be open to the complexities, contingencies, and uncertainties of common cultural experience. For example, given the burgeoning of global sports spectacles and infrastructures, mediated sports is a highly suggestive test case for globalization theory. The extent to which global sports may be emerging, or the ways in which local or indigenous sports may survive or adapt to the changes precipitated by commercial media sports, are important concerns. The failure of predominantly American sports like baseball and gridiron to become truly global despite heavy promotion by media sports corporations, for instance, or the corresponding slowness of the world game, soccer, to consolidate itself commercially at the highest level in the US despite that country's hosting in 1994 of the massive media spectacle of the World Cup, demonstrate how social and cultural groups do not simply accept – and may even actively resist – the media sports made commercially available to them for their consumption. Important to the dispersion and establishment of sports around the world are the specific histories of the relationships between different countries. For example, international cricket developed in the Indian subcontinent, sub-Saharan Africa, Australasia, and the Caribbean according to the southerly trajectory of the British Empire. Until the end of the twentieth century, cricket was dominated by white former imperial and colonial powers, but the growth of the Indian media sports market has been so marked as to shift the international balance of the game in a decidedly postcolonial direction. In the twenty-first century, India does not only control the International Cricket Council, but has produced a new kind of media sports spectacle in the Indian Premier League that incorporates the visual sumptuousness and high-energy musical routines of Bollywood cinema (Rowe, 2011).

The relationships between media sports texts and audiences are made available for analysis in more open, less culturally pessimistic ways by those scholars who emphasize that media sports texts have multiple meanings (Brookes, 2002), and that audiences can be active and agentic. Instead of seeing sports *aficionados* as inevitably victimized and exploited, then, greater allowance is made in culturalist approaches for how audiences might actively experience and negotiate their encounters with the sports media. For example, the pleasures that women may take in viewing male sports can be viewed from this perspective as a legitimate leisure choice, rather than as an inevitable sign

of patriarchal domination and commercial media domination. Similarly, the a priori assumption that the media sports gaze of fans is inevitably controlled by capitalist interests for their own acquisitive ends can be challenged by examining the ways in which sports fans cooperate to assert their own power or act in ways that are quite distinct from the projections of sports promoters and marketers despite the full armory of media persuasion devices at their disposal.

There is a danger, however, that such discoveries of empowered, active media sports audiences may exaggerate the degrees of freedom of choice of the socially disadvantaged and act as a smoke screen for persistent social inequality. For this reason, it is necessary for continuing social scientific scrutiny both of the density of representations of human subjects in mass media sports (who is most visible) and of their differential social quality (how are they depicted). A striking illustration of this point is the conventional neglect of women's sports in the print and electronic media, such that it remains stubbornly less than 5% of total sports coverage in even the most mature media sports markets, and which is compounded further for women of color, while the sexualization of the bodies of sportswomen is still routine media practice (Scraton and Flintoff, 2002). Hence the role of mass media sports in the stereotyping, marginalization, and disempowerment of subaltern groups can be approached through a judicious combination of quantitative (including content analysis and audience statistics appraisal) and qualitative method (such as ethnographic studies of media sports audiences and textual analysis of media sports imagery). Forms of research and analysis with a cultural emphasis, when informed by a political economic perspective, remain the most promising current lines of inquiry into mass media sports.

These approaches (summarized for the purposes of clarity in **Table 1**) come together productively in the critical interpretive tradition that explores the relationship between major forms of social inequality and media sports representation. A key case in point is the rather anomalous celebration of African-American masculinity in sports like basketball in the context of persistent racism and racial disadvantage in the USA (Carrington, 2010). Others include the continuing ascription of sporting and related capacities, both positive and negative, according to race, ethnicity, or through the racialization of Muslim athletes after the 2001 destruction of the World Trade Center. Another fault line that is available for critical interpretive analysis is the media representation of sexuality in sport (Miller, 2001), including the frequent treatment of athlete homosexuality in the language of scandal. Indeed, the intermittent eruption of mediated sports scandals in general provides rich, varied opportunities for scholars to engage with both the substantive question and the media's (including, but not limited to, the specialist sports media's) handling of it. These pretexts for analysis range from scandals and controversies that are institutionally serious (such as corruption in the IOC and FIFA, or China's treatment of Tibetan human rights in the lead-up to hosting the Olympics) to those that are pruriently voyeuristic (like the infidelities of golfer Tiger Woods) but which, nonetheless, can help stimulate debates over issues concerning gender or the manufacture of celebrity image. That such divergent avenues of inquiry exist attests above all to the sheer scale, complexity, and dynamism of the media sports cultural complex.

Table 1 Comparison of political economic and culturalist analytical approaches to mass media and sports

Political economic	*Culturalist*
Economic ownership and control of sport and media	Symbolic meaning and use of sport and media
Quantitative method	Qualitative method
Social class position	Multiple identities
Centralized model of power	Diffused model of power
Domination and manipulation of media sport audiences	Contestation and negotiation by media sport audiences

New Media, Future Sports, and Research Trajectories

Mass media and sports are now firmly established as a focus for many social and behavioral scientists, whose number grows alongside their subject. The period of relative stability that characterized the previous three decades has ended with the coming of digitization and media convergence, and what can be called 'networked media sport' (Hutchins and Rowe, 2012). As the dominance of broadcast television is eroding with the proliferation of screens and platforms, it is now necessary for researchers, like media sports audiences, to be flexible, agile and dedicated to multitasking. Data collection is becoming more difficult. Recent market-based research has claimed that the Internet is now the preferred media sports platform among 18- to 35-year-olds in Europe. But the widespread practice of polymedia use, including social media, is revealing a more complex media sports attention economy in which singular technologies and platforms operate in different media permutations. Under these circumstances, it is not only difficult to separate sports from their representation (as mediatization takes further hold), but the emergence of 'produsers,' such as citizen journalists, is breaking down the distinction between media sports producers and consumers, as well as between professionals, hobbyists, and amateurs. These trends have prompted increasingly vigorous debates between social scientists over the power of media sports corporations that have been contrastingly adjudged to be in either complete control of media sports consumption or mere service providers subject to the whims of sovereign consumers. Therefore, there is continuing contestation over the connection between mediated sports and cultural citizenship rights as more premium sports television is acquired exclusively by subscription-based platforms at the expense of public and commercial free-to-air audiovisual services. There is also research and analytical exchange over the extent to which media sports producers are being subjected to surveillance so that they can be more effectively tracked and targeted in their consumption behavior, as well as being exploited as unpaid labor that produces much of the additional content of sports Web sites that are owned by private companies, and rely on the generation of traffic for their profitability.

The explosion of the quantity and range of mediated sports, and the inextricable nature of the media–sports nexus, means

that the task of analyzing their content, meanings, and uses, and their corresponding link to sociocultural structures and practices, is commensurately enlarged. This is the case not only when global media sports spectacles carry a profusion of images of nations and bodies (Tomlinson and Young, 2006), but applies to the seemingly mundane news reports that insinuate sports into the daily stock of events selected by the media as worthy of coverage, as well as to the deployment of sports metaphors in advertisements and of sportslike competitive frameworks in very different media genres. Such academic work requires the full spectrum of social and behavioral science research methods ranging from quantitative content analysis to ethnography, from political economic inquiry to discourse analysis. Without this breadth of research, the media sports cultural complex will be perversely inescapable and yet inexplicable.

Mass Media: Introduction and Schools of Thought

Peter Dahlgren, Lund University, Lund, Sweden

This article is reproduced from the previous edition, volume 14, pp. 9350–9358, © 2001, Elsevier Ltd.

Abstract

After a brief discussion on the varying nomenclature applied to the field, this article discusses the two basic orientations: academic and applied. From there, the discussion takes up the sprawling character of the field, underscoring that the field can be conceptually organized in a variety of ways. The main part of the discussion consists of a presentation of four major schools of thought. These are defined as: (1) the mainstream perspective, which derives from the postwar US social sciences; (2) the critical tradition, which comprises several different strands; (3) the culturalist approach, which also blends elements from various intellectual sources; and (4) policy horizons, which deals with central issues such as ownership structures, financing and regulation. The article concludes with brief reflections on possible future developments of the field.

The term 'the mass media' refers to institutions that via technologies of largely one-way communication, reach audiences that consist of large numbers of people. The book can be seen as the first mass medium and consequently it could be argued that mass media emerged with the development of printing as a medium at the end of the fifteenth century. However, the concept of the mass media is normally associated with the development of modern, industrial society in the West, beginning in the early nineteenth century. In this period, newspapers joined the book as an important mass medium; later in the century, the telegraph became an important point-to-point media technology that had important consequences for the mass media via its conjunction with the press. In the twentieth century, film, radio, phonograms, and then television and video were added. The growth of the media has of course always been conditioned by prevailing historical circumstances (Winston, 1998) and how they are to be best used remains at the core of ongoing media policy issues. The spread of the mass media has proceeded in an accelerating manner and today they constituent a central feature of modern society. From the micro-level of individuals in everyday life to the macro-level of societal institutions and processes, including the global setting, modernity is inexorably intertwined with the development of the mass media (Thompson, 1995).

The Field

While research about the mass media can be traced to the early decades of the twentieth century, mass media studies first arose as an academic field during the 1950s, establishing itself institutionally in the following decade, first in the US and then elsewhere. Emerging from several disciplines in the social sciences and humanities, the field launched its own academic departments, journals, associations, and conferences. In the US today, most colleges and universities have departments offering courses and programs about the mass media, a pattern that is increasingly manifested in other countries as well. The field today is broad and eclectic, reflecting both the influences of its earlier intellectual origins, as well as the newer developments in the media's evolution and changing socio-cultural significance.

Mass media studies manifest a heterogeneous collection of theories, methods, and general intellectual profiles (see McQuail, 1994 for a useful overview; Boyd-Barrett and Newbold (1995) provide an extensive collection of key texts in the field). Academic departments go under a variety of names, emphasizing different angles on the field, e.g., in the US, many departments have their origins in the older schools of journalism, others developed out of speech communication and rhetoric, others from sociology or literature, and so forth. Programs in journalism studies and training are often coordinated with more general mass media studies, while film history and film studies more generally often tend to maintain a separate institutional identity. Particularly in the UK, the field of mass media at universities is often linked with cultural studies.

Nomenclature

The labeling of the field varies to some extent. In some academic departments, the dominant thematic is 'communication,' and mass media studies, treated as 'mass communication' may be juxtaposed to such areas as interpersonal communication, organizational communication, and intercultural communication. In the last decade or so, particularly in the light of newer developments in digital media technology that make possible more interactive modes of communication, there is a tendency to drop the adjective 'mass' and simply refer to media studies. This inclination is also prompted by changes in social theory: the term 'mass media' is seen as echoing older theories of 'mass society,' a perspective that today appears out of step with the complexities of contemporary social realities.

Two Basic Orientations

As a field of teaching and research, mass media studies tends to encompass two basic orientations. On the one hand is academic research and a critical liberal arts perspective on the media and their relationship to society and culture, often aimed at answering scientific questions about their institutional operations, their output, and their audiences. On the other hand one finds an emphasis on applied knowledge. This can be geared to the many operational questions facing media

industries, to various organizational actors that make use of the media for their own purposes (corporations, political parties, interest groups, etc.), and to occupational practices within the media. Such occupational practices include production skills within the different media, as well as professional training, in particular for journalism. Other occupational orientations include public relations, advertising, and media management. The lines between the academic and the applied orientations are by no means fixed; the interplay between the two can be both productive as well as problematic. Outside the academy there is considerable media research done from commercial horizons, for example market research, audience measurement, and studies on the effects of advertising. Also, political actors have increasingly been making use of media consultants for strategic purposes.

Organizing Logics

While mass media studies is a rather sprawling field, there are several organizing logics that give it some structure and coherence. These logics are not mutually exclusive, nor do they have equivalent status. However, they can serve as partial maps of the research terrain. The first such logic derives simply from specifying a particular medium. Many people in the field will identify themselves for example as researchers of television, radio, or the press. Others will specialize still further and focus, for example, on television history or the television industry. Many research studies, however, may encompass more than one medium, for example in a case of the analysis of news coverage.

A second logic is to emphasize the different elements of the communication process: a basic model of communication will often use the elements 'sender,' 'message,' and 'receiver.' Translated into the context of the mass media, this yields, respectively, studies of media institutions, media output, and media audiences. Research on media institutions examines the conditions, both internal and external, that shape the way they function. This can encompass for instance questions about regulation, political influence, and organizational routines. The study of media output includes the form, content, and modes of representation. Often specific genres, particularly television genres such as soap operas and talk shows, become the object of sustained research attention. Studies of media audiences can include analyses of the impact of specific output, the uses which people make of it, and the interpretations they derive from it.

Third, specific topics or themes provide ongoing structure to the field. These themes can be broad, such as media effects, or (more specifically) media effects on children. Many themes link media studies with particular topics on the wider social research agenda, such as gender and ethnicity; health communication, media and social movements, and media and sports, are also examples of such specialization. Some themes derive instead from particular theoretical and/or methodological developments, for example, agenda setting, media events, or media uses and gratification, and can be applied to a variety of empirical areas.

A fourth organizing logic derives from the still-remaining links between mass media and the 'parent' disciplines; such links serve to focus research (and connect researchers) from particular disciplinary perspectives. For example, political communication is a subfield that interfaces with political science, often incorporating public opinion studies; the psychology of communication examines cognitive processes in relation to mass media. Often, however, within the overall field of mass media studies, intellectual lineage is not made explicit, given that the field has developed a distinct identity over the course of several decades.

Finally, weaving through the above logics are sets of intellectual traditions that very loosely structure the field into schools of thought (see below). It should be emphasized that 'school' is used loosely here; it points to tendencies within the field, not unified factions with clear demarcations. These schools basically reflect differing theoretical and methodological orientations; they point to general intellectual dispositions. The relationships among them have evolved over time, and the development of the field can be understood to a considerable extent by looking at the emergence, interface, and transitions of these schools of thought.

While the exact labeling may be differ in historical accounts of the field, the following constitute the main schools of thought within mass media research: the mainstream perspective, the critical tradition, the culturalist approach, and the policy horizon.

The Mainstream Perspective

The systematic study of the mass media arose in the early decades of the twentieth century, and the mainstream perspective today can be understood as the intellectual descendants of the pre-World War II pioneers. While the mainstream perspective encompasses a wide array of research orientations and is continually developing new approaches, it is united in its basic adherence to traditional social scientific methodologies and approaches to theory. Its intellectual underpinnings are found chiefly within sociology, psychology, and social psychology, and it constitutes the still-dominant tradition of empirical research in mass communication.

Origins

Its origins can be found in nineteenth century sociological conceptions about the crowd and the mass; early research efforts and attempts to develop theory were geared toward among other things the theme of propaganda, with the experiences of World War I as a point of reference. In the 1920s, the Chicago School of sociology, with its German-trained prominent member Robert E. Park, developed a strongly qualitative, ethnographic micro-sociology of mass media uses and impact, within a generally progressive and reformist social vision. Walter Lippman's (1922) theories about public opinion were an important element in conceptually linking the mass media with the processes of democracy.

The political scientist Harold Lasswell, in the 1930s under President Roosevelt's New Deal, saw new opportunities for studying public opinion and propaganda. His formula of 'who says what to whom through what channel and with what effects' served as a framework for media studies for many years. In psychology, Kurt Lewin's psychology of personality and of group

dynamics foreshadowed analyses of the social processes of media influence. After the war, Carl Hovland and his associates (1953) further developed behaviorist perspectives on persuasion.

Interest in the media grew in step with their expanding role. The imperatives of the wars, the importance of the media in political processes, concern about the media's impact on psychology, emotions, and behavior, as well as increasing commercial concerns of the media themselves stimulated research. After World War II, functionalist sociological theory had become the dominant paradigm for fledgling media research, backed up by developments in methodological techniques. Quantitative content analysis, aimed at mapping the manifest dimensions of media messages, became the norm for studying output. Studies of audiences' media preferences, and, most importantly, effects of the media on audiences, began to blossom. Surveys became an established approach; later the strategy was developed to repeat surveys with the same respondents to yield panel studies over time (see Rosengren and Windahl, 1989).

A key person in the USA at this time was the Austrian-born Paul Lazarsfeld, who was active in ushering in a new phase of mass-media research. Lazarsfeld began working for the commercial media in the 1930s, and he viewed the media research tradition he helped to develop as 'administrative' research. This was geared to serve the strategic purposes of media institutions. Gradually, a more society-wide perspective emerged, that helped shape a media-research orientation that was in harmony with the consensus assumptions about society. Together with Elihu Katz (Katz and Lazarsfeld 1955), Lazarsfeld helped introduce the notion of how the impact of the media is filtered through social interaction with others, giving rise to the concept of the two-step flow of communication. Wilbur Schramm (1970), in the 1950s and 1960s, did much to synthesize the diverse elements and promote the identity of mass media research as a distinct field of inquiry.

The Golden Age: Effects Research and Content Analysis

From about 1950 to the early 1970s, the mainstream perspective emerged, solidified, and remained essentially unchallenged. This was its golden age; since then the heterogeneity of the field has increased. During the 1950s, concern with the effects of the media continued to grow in the USA, especially in the light of television's reach into just about every home. The questions around media effects were not merely scientific: there was popular concern about violence and the media and about portrayals of sexuality, and, later on, about pornography. The media industries landed in a seemingly paradoxical position of trying on the one hand to soothe popular opinion by asserting that such negative effects were minimal, while on the other hand assuring the advertising industry of the effectiveness of media messages. There was also a malaise about 'media manipulation' in the realm of politics, as the question of just how much the media shape attitudes and opinions took on increasing concern. A landmark book in this context was Joseph Klapper's (1960) *The Effects of Mass Communication*, which argued for a 'minimal effects' position.

Within the media effects research tradition, the nature of the 'effects' investigated can vary considerably: on beliefs, attitudes, knowledge, or behavior; intentional or unintentional; long-term or short-term; and so forth. In the USA, the Surgeon General's massive, multivolume report (1972) was perceived to be inconclusive by many, but what it did emphasize was the importance of so-called intervening variables. That is to say, the effects of the mass media must be understood as being qualified by such factors as age, gender, education, social circumstances, audience contexts, and so forth. Generally the drift in media effects research has been away from the earlier psychologism toward increasing socio-cultural complexity. Concern with the effects of mass media continues today, even if the task of identifying and isolating specific media output and linking it to particular effects becomes all the more difficult with the increasing mediatization of society.

The mainstream perspective has been no less interested in the nature of media output. Journalistic output is one of the major areas in which content analysis has been applied, where bias in reporting has been studied by measuring, for example, the visibility of opposing candidates during election campaigns, and coding degrees of positive and negative valence. More encompassing studies have been done where researchers have attempted to elucidate important dimensions of journalistic coverage or even in fictional portrayals that are normal or routine, yet may remain invisible precisely because of their everyday, taken-for-granted character. Measurements have been developed, for example, for tallying acts of violence in television programs. The ambitious Cultural Indicators project of George Gerbner (1973) and his colleagues sought to illuminate the symbolic world of TV fiction in the USA, mapping not only violence, but the more general norms and values manifested in the programs.

Within the tradition of so-called agenda-setting research (see Dearing and Rogers, 1996 for an overview), news and current affairs in the mass media are studied and then compared to audiences' understandings of, for instance, what are the major issues of the day. The comparison allows researchers to draw conclusions about the extent to which the media set the political agenda; generally the findings are that the media do have this initiative, but it has been found that audiences, or rather the public, do not always simply mirror the concerns of media coverage.

Tensions in the Field

The mainstream perspective continues to develop, partly in response to new phenomena in the media, e.g., we witness today considerable attention to the transnational character of the media and a growing research concern with political advertising (Bennett, 1996). However, innovation in theory also generates renewal. Thus, in the 1970s the uses and gratifications tradition (Blumler and Katz, 1974) arose and posed a set of complementary – if not fully competitive – questions to the effects tradition. Basically, instead of asking what the media do to people, the newer orientation asked what people do with the media and what satisfactions do they thus derive. This shift points to an ongoing key tension within the field, namely the question of the relative power of the media and the degree of autonomy of the audience. The view of minimal effects, in keeping with the intellectual origins of functionalism, liberal democracy, and the needs of commercial media had strong support but did not go unchallenged. Indeed, critics began

claiming that the theories and methods embedded in the mainstream perspective structured a status-quo perspective toward media and society (Gitlin, 1978). In 1983 and again in 1993, the leading US journal in the field, *The Journal of Communication*, had themed issues on the tensions within the field (Gerbner, 1983, Levy and Gurevitch, 1993).

It should also be noted that the prevailing conception of the process of communication at work within the mainstream perspective, operating for the most part implicitly, was that of the transfer of messages or, more generally, of information. This view has its origins in, among other things, Shannon and Weaver's (1949) cybernetic view of communication. Gradually this basic model was augmented by contributions from cognitive psychology, giving rise to more elaborate notions of human information processing. Yet, other voices, with an anchoring in the humanities and cultural theory, were challenging such views, arguing for the centrality of meaning for the process of communication. Both the critical tradition and then the culturalist approach began to coalesce and to offer competing paradigms of mass media research.

The Critical Tradition

During the late 1960s, critical traditions from various strands of neo-Marxism were beginning to make themselves felt within the social sciences, and by the early 1970s they were manifesting themselves in mass media studies. There are several intertwining intellectual strands here: political economy, the critique of ideology and public sphere theory.

Political Economy

Though the political economy of mass media need not a *priori* be based in the Marxian tradition, within media studies the term does most often connote this lineage rather than, say, neoclassical political economy or conventional economics. The emphasis in Marxian political economy of the media is often on the links between economics and the social, political, and cultural dimensions of modern life; pluralist or consensus models of society are generally rejected as inaccurate. A recurring thematic is the tension between on the one hand, the capitalist logic of media development and operations, and on the other, concerns for the public interest and democracy. The political economy of the media does not anticipate the elimination of commercial imperatives or market forces, but rather seeks to promote an understanding of where and how regulatory initiatives can establish optimal balances between private interest and the public good. The work of the Canadian scholar Dallas Smythe (1977) was an important element in the development of this tradition; among contemporary researchers Nicholas Garnham (1990) has further expended the perspective, which has in turn been systematized in Mosco (1996). Within this perspective, the emphasis is most often on the institutional arrangements of the media: ownership, control and regulation, and their consequences. The political economy of media structures at the global level has increasingly come under research scrutiny (e.g., Herman and McChesney, 1996).

A variant of the political economy tradition has focused on media imperialism, in particular how the combination of US corporate and political interests over the years have made use of the media abroad and the consequences that this has had for people in other countries, particularly the developing nations. The work of Herbert Schiller (1976) has been central here. Media flows from the West to 'the Rest' were plotted (Nordenstreng and Varis 1974), including fiction, other entertainment, journalism, and also the role of international advertising (Mattelart et al., 1984). Unesco became a political forum and research promoter for a New International World Information Order (1980). Such research was framed by historical circumstance: the bipolar East-West situation of the Cold War shaped US media strategies abroad in ways that had impact on the North-South global divide. Since the collapse of communism, the North-South socio-economic gap has continued to grow, and though the transnationalization of the mass media is now often framed analytically within paradigms of globalization, critical attention is still addressed to global media disparities.

The Critique of Ideology

Another strand of critical endeavor attends in more detailed ways to media representations, analyzing them from the standpoint of their ideological dimensions. The intellectual roots for the critique of ideology derive not only from Marx, but also from the structural neo-Marxism of Althusser, as well as the more culturally oriented versions of the Frankfurt School's Critical Theory and of Gramsci. Methodologies and epistemologies were at times in conflict, not only between the mainstream perspective and the critical tradition, but also within the critical tradition. Versions both of cultural Marxism and of structural Marxism – the latter making use of Freudian theory adapted via Lacan – became incorporated into the development of cultural studies (see below). A landmark effort in the critique of ideology in media studies was the work of the Glasgow Media Group (1976), which made explicit use of traditional social science methodologies of content analysis to make its points about the class bias of the British Broadcasting Corporation's journalism.

Ideology as such is a slippery concept, and the earlier assumptions about false consciousness could not hold up to critical scrutiny and increasingly sophisticated epistemology. Gradually, the critique of ideology began to make use of the hermeneutic tradition, treating ideology as an aspect of the interpretation of meaning in the reproduction of relations of social domination. The critique of ideology began to blend with cultural theory, signaling a growing entwinement of the critical and culturalist schools. Efforts to analyze cultural hegemony, in both its domestic and transnational manifestations, strove to relate media representations and the political economy of the media to specific social circumstances. Also, the growing presence of feminism within the critical tradition began to render the exclusive concern with social class as the foundation of ideology untenable: ideology could manifest gendered social relation, not least in the media. Gradually, feminist perspectives began to take hold in media research (van Zoonen 1994). Also, race and ethnicity also became foundations for the critique of ideology in the mass media (Gandy 1998).

Public Sphere Theory

Discussions of democracy and the media are increasingly framed within the concept of the public sphere, a concept associated with Jurgen Habermas (1989, see also Calhoun 1992). In schematic terms, a public sphere is understood as a constellation of institutional spaces that permit the circulation of information and ideas. These spaces, in which the mass media figure prominently, also serve to foster the development and expression of political views among citizens as well as to facilitate communicative links between citizens and the power holders of society. Beginning in the 1970s, media researchers in Europe and later, the USA, began using the concept to pursue critical analyses of mass media, examining the factors that impede the public sphere. The concept has many parallels with the liberal notion of the 'marketplace of ideas' and similar metaphors, and today it has entered into more mainstream usage, where the problems of journalism are discussed and researched; its Frankfurt School origins often remain in the background.

The Culturalist Approach

Within mass media research, contributions from the humanities and from qualitative, interpretive social science had long remained in the shadow of the dominant social scientific methods. Studies based in literature, history, rhetoric, or anthropology were very much the exception. Marshall McLuhan's (1964) work, with a historical view of media technology, was an exception, but it had more impact outside the university than within academic media research.

Cultural Studies

In the 1960s British Cultural Studies was in its formative years, and in the following decade, under the leadership of Stuart Hall (Hall et al., 1980) had begun to impact on media research (Turner 1996). The eclectic synthesis of intellectual ingredients in cultural studies – including neo-Marxism, structuralism, feminism, psychoanalysis, semiotics, and ethnography – was applied not only to the media but a range of topics having to do with contemporary culture and society. In particular, popular culture has been an ever-present topic of research and debate. Cultural studies has among other things shifted the focus of issues around popular culture (and/versus high culture) from earlier largely aesthetic concerns to questions about social relations and power; taste becomes socially contextualized. There has also been a 'rehabilitation' of popular culture, where 'the popular' is seen as no longer so clearly demarcated from high culture or, alternatively, is defined in a manner to give it political relevance (Fiske, 1989). Other research takes the ways in which the media, via advertising and general lifestyle imagery, are central to contemporary consumer culture, not least on the global level (Featherstone, 1995).

Cultural studies has grown into a heterogeneous, multidisciplinary field in its own right, with contributions from currents such as postmodernism and postcolonialism, among others. Today studies of the media are only a small part of its vast concerns. Cultural studies can be seen as part of a larger 'cultural turn' within the human sciences in recent decades, but today it is clearly the dominant culturalist tendency, even if there is a lack of consensus about both its core and its boundaries. As cultural studies has expanded and become a global academic phenomenon mingling with many other academic traditions, the critical character of its earlier years, where issues of social and semiotic power were thematized, has not always remained evident. For example, the emphasis on the multiplicity of interpretations of popular culture – at times augmented by postmodern perspectives – has tended to undercut arguments about ideology.

The Centrality of Meaning

In culturalist mass media studies two themes from the humanities and qualitatively oriented social sciences have come to assume central positions: sense-making and social constructionism. Research has come to deal with questions of how media representations convey meaning, how media audiences make sense of these representations, and how media-derived meanings further circulate in society. Hall's (1980) model of how meaning is encoded by the media and decoded by audiences became an important organizing concept for much of such work. Studies of reception – how audiences interpret what they encounter in the media – became an important subspecialty within mass media research; the work of Dave Morley (1992) and Ien Ang (1985) are significant contributions in this tradition. Generally, as the media landscape becomes more multidimensional and theorizing about the audience becomes more ambitious, the frontlines of audience research manifest both a convergence of different research approaches and a growing complexity. (e.g., Hay et al.,1996)

If semiotics and hermeneutics were the major text-analytic tradition within cultural studies, today they have become augmented and partly replaced by innovations from various other currents such as linguistics and cognitive psychology. These newer efforts have coalesced to generate several versions of what is now termed discourse analysis (van Dijk, 1997) that is increasingly used in the elucidation of meaning in media texts.

Active Subjects

In culturalist approaches to the mass media, the emphasis on the production of meaning and social constructionism tends to privilege versions of the active subject. This perspective is manifest not least in a strand of research that has underscored the audience's sense-making, though debates have emerged (again) as to the degree of semiotic power that should be accorded the audience relative to the media (Curran, 1990). Research in some quarters has linked audiences' interpretation of the media as forms of cultural resistance, and tried to delineate interpretations that run counter to hegemonic trends; Radway's (1984) study of women's uses of romance novels for a variety of purposes is a compelling example. More generally, theories of subjectivity have been mobilized to study how individuals construct identities via their active appropriation of media; feminist contributions have been particularly visible here. From the standpoint of collectivities,

mass media and cultural identity has become a growing domain of research, not least in transnational contexts (Morley and Robins, 1995).

The Policy Horizon

It could be argued that the policy horizon is not a school of thought, but rather a thematic organizing logic encompassing diverse perspectives. However, the centrality of policy in the shaping of media development and the distinctiveness of its concerns speak for its status as a school.

Media Systems and Norms

Situated in the force fields between economics, politics, and technology, the way the media are owned, organized, and financed, and the way that they operate have much to do with the vicissitudes of the policy process. Policy is of course shaped by the specific interests and actors involved, such as the state, commercial media institutions, the advertising industry, media production organizations, citizens groups, and other representatives of the public interest. One line of policy research has addressed the historically anchored traditions in political culture and in philosophies of the public good that buttress prevailing normative frameworks in regard to the media. These frameworks are generally accepted but often given competing interpretations. Freedom of the press, for example, has had a particularly strong status in Western liberal democracies, though how it is to be best applied in a concrete case may be contested. Historically, and today globally, there are competing models for media systems, including authoritarian, communist, and social responsibility versions that build upon differing sets of norms.

Regulation and Deregulation

Another line of research has been more engaged at the frontlines of ongoing policy issues and battles, and often seeks explicitly to intervene in the policy process. The growing concentration and conglomerization of media ownership has been charted by liberal critics in the USA (Bagdikian, 1997), and elsewhere; generally much of the political economy perspective has fed into policy research. Over the past two decades, the increasing commercialization of media industries, coupled with a political climate shaped by neoliberalism, has contributed to a massive deregulation of the media, giving market forces ever greater free play and repositioning audiences less as citizens or as a public and more as consumers. This has been especially true in the realm of broadcasting regulation, and in Western Europe public broadcasting has undergone a radical realignment as it has lost its monopoly position (Tracey, 1998). For over two decades the Euromedia Research Group (1998) has studied these developments. Confronted by commercial channels borne first by cable and satellite systems, and then terrestrial stations, public broadcasters in Europe and elsewhere find that their *raison d'etre* has to be redefined as they look to the future. Public broadcasting emerged as a part of the project of the nation-state, and its current circumstances can be seen as part of the dilemmas facing the nation-state in the era of globalization. At the transnational level, the regulation of international communication becomes all the more important – and complex.

The global media landscape today is dominated by fewer than two dozen conglomerate giants who increasingly control the production of media output and the distribution process, as well as the technical infrastructure. Technical advancements promote a convergence between the technologies of broadcasting, telecommunications, and the computer. Institutionally, major companies in the computer and Internet field have begun to merge with the giants of the traditional mass media. This evokes profound policy issues of diversity, accountability, and democracy (McChesney, 1999).

Looking Ahead

The media are obviously in transition, and research is in the process of adapting itself to the emerging realities. The increasing on-line presence of the traditional media, as well as other forms of functional integration technical convergence, suggest that the field of mass media research will in particular increasingly take on a digital focus. There will be growing attention to such areas as the information society, computers and society, human-computer interface, and electronic democracy. Digitalization has prompted a flurry of research from many disciplines, including social theory (Castells, 2000) and thus it can be argued that the field of mass media research will increasingly blend with initiatives from other directions. This may involve some erosion of its status as a separate field, but the enhanced attention being paid to the media will no doubt increase our knowledge and understanding of them.

Abstract

Political economy is an intellectual project, and effort to develop a model of social order and change. Political economy set out to understand how capitalism worked and assess its consequences for the organization of social and political life. The central question that a political economy approach asks is how public communications' embedded in a capitalist economy based on private enterprise, affect its ability to provide disinterested information, plural viewpoints, open debate, and communal culture required by democratic theory? The central assumptions of the perspective and its questions is at the center of this article.

The Birth of Political Economy

Political economy first emerged as an intellectual project in the eighteenth century as part of the Enlightenment's concerted effort to replace religious and metaphysical accounts of the world with rational, man-made, models of order and change. As a building block in what was later to become the 'social sciences,' political economy set out to take the new machinery of capitalism apart, find out how it worked, and assess its consequences for the organization of social and political life. Following the revolutionary upheavals in America and France, these connections came to center more and more on the material and cultural conditions required to secure a democratic social order in which people were no longer subjects of a monarch or an autocratic ruler, but were autonomous citizens. This new status conferred rights to participate fully in social and political life and elect the representatives making the laws by which they consented to the obligation to balance individual advancement against contributions to collective life. Envisioning a society of citizens lay at the heart of the Enlightenment's emancipatory project of banishing ignorance, fear, and exploitation and promoting the rational pursuit of liberty, equality, and fraternity. This ideal continues to provide political economy with its moral touchstone positioning many of its practitioners as critics of capitalism's failure to reconcile possessive individualism with the common good.

Capitalism, Democracy, and Communications

It was immediately clear to many observers, that the emerging system of public communications, centered at that time on the daily press, had a pivotal role to play in securing a democratic social order. First, it provided the most effective way of disseminating the information and knowledge citizens needed to understand the problems facing society and how these might be tackled. Secondly, it offered a communal space in which alternative interpretations of the situation and competing policies could be tested against the available evidence. Thirdly, by overcoming geographical separation it helped construct the nation-state as an imagined community of citizens as well as an administrative apparatus.

By the mid-nineteenth century however, it was equally evident that communication systems also played a pivotal role in organizing the new industrial forms of capitalism. First, they provided the infrastructural supports that allowed firms to track and coordinate activities that were becoming ever more diverse and dispersed. Secondly, they provided new outlets for display advertising that was increasingly central to the task of matching supply to demand. Thirdly, they offered enticing opportunities for capitalist enterprises in their own right. As migrants moved into the cities to work in the new factories and offices, the demand for popular reading matter and later for recorded music and cinema, grew exponentially.

The central question that these developments posed for political economy was deceptively simple: 'How did public communications' increasing integration into a capitalist economy based on private enterprise affect its ability to provide the disinterested information, plural viewpoints, open debate, and communal culture required by democratic theory?

A Free Market in Ideas

For the first half of the nineteenth century most commentators argued that the best guarantee of reliable information and open democratic debate was a free market in ideas and arguments, in which a plurality of publishers competed for readers with minimum interference from the state. There were good reasons to identify the state as the principal enemy of press freedom. In England, the government had introduced an array of compulsory levies on the press (including taxes on the paper used and the advertisements) in an effort to make radical publications economically unviable. The battle to repeal these 'taxes on knowledge' (as they were known) lasted until 1869, when the last remaining provision was abolished. However, it was at exactly this point, when the nominal freedom to enter the newspaper market was extended, that the introduction of new production technologies (improved presses, mechanized composition, and new graphic capabilities) rapidly raised the price of market entry and began to concentrate press ownership in the hands of wealthy individuals. This development placed a sizable question mark against the press's ability to fulfill its promise of acting as a watchdog on abuses of power. In their pamphlet of 1846, *The German*

Ideology, Karl Marx and Frederick Engels had famously argued that the capitalist class's control of economic resources allowed them to 'regulate the production and distribution of the ideas of their age' and manipulate public culture in their own interests. Witnessing the rise of the new 'press barons,' even commentators who rejected revolutionary politics began to wonder if Marx might not be at least partly right. Most of the old style proprietors had owned a single title, which they often edited themselves. The new press owners commanded chains of titles stretched across key geographical markets. Moreover, the increasing importance of advertising seemed to many observers, to be extending the influence of capital still further. Drives to maximize readership among the urban working class had led to cuts in cover prices and the spread of the 'penny press.' Shortfalls in income were made up by advertising revenues, altering the previous relations between paid publicity and editorial matter. As the English commentator, Thomas Bowles, noted in 1884: "Newspapers … profess to sell news and give advertisements to boot. What they really do is sell publicity … and give news to boot."

The emergence of a press system funded primarily by advertising whose ownership was increasingly concentrated in fewer and fewer hands challenged the ideal of public communications in the service of democracy in several ways. Firstly, it raised the possibility that proprietors might use the titles they owned to promote their own political enthusiasms or business interests while denying space to opponents and critics. Secondly, dependence on advertising revenue opened newspapers to editorial pressure from large advertisers wishing to promote their activities or censor unfavorable publicity. Thirdly, the growth of advertising content privileged the speech of commerce and squeezed the space available to other voices. Fourthly, because advertisers required access to either mass readerships or wealthy niche markets, publications catering to marginalized minorities or less-affluent groups became ever more precarious or unviable. Surveying the situation in the United States in 1910, Edward Ross, reluctantly concluded that 'the commercial news-medium does not adequately meet the needs of democratic citizenship.' Many of his contemporaries agreed, but saw the entrenched identification of a free press with a free market as an immovable barrier to reform. As Delos Wilcox lamented in 1900: "The American people must dearly love the freedom of the press, or we should have heard before now much talk of government control or operation of the newspaper" (Wilcox, 1900).

The growing tensions between the communication system's centrality as simultaneously a resource for capitalist expansion and a support for democratic culture prompted two reactions. Some analysts set out to develop a political economy of public communication, measuring corporate performance against the requirements of democratic theory. Others, like Alfred Marshall in his *Principles of Economics* (1890), announced the death of political economy and birth of 'economics.'

Political Economy and Economics

By dropping the adjective 'political,' economists measured their distance from political economy in three ways. Firstly, where political economists set out to trace the general consequences of shifts in economic organization for social and cultural lives, economists focused on the working of 'the economy' defined as a separate, bounded, sphere. Secondly, because economists saw economic behavior as the product of a universalistic individualist psychology rather than of socially constructed institutions, they generally avoided critical reflection on prevailing institutional arrangements and possible alternatives to them. They saw the economy as a set of interlinked markets, and not as a system of power. Thirdly, they defined their role in technical terms and detached themselves from political economy's engagement with moral philosophy. They were concerned with efficiency rather than justice, with individuals as consumers rather than citizens. The field of mass media research is still deeply marked by this division.

Media economists are primarily interested in the peculiarities of the communication industries as industries and tend to see regulated markets as the least worst way of organizing them. In contrast, critical political economists of media have tended to focus on market systems' failures and distortions in the cultural sphere and to champion various forms of public intervention. They begin with the possession of core forms of capital (both material and symbolic) rather than with the dynamics of exchange.

Institutionalizing the Public Interest

In 1808, Thomas Jefferson's Treasury Secretary, Albert Gallatin, argued strongly for federal control of America's developing road and canal system on the grounds that they would befit everyone by uniting 'the most remote quarters' of the nation, both physically and imaginatively. Later observers saw the same potential in the telegraph and the telephone, arguing that these new media markets were 'natural monopolies' because a single operator was likely than competing firms to optimize both economic efficiency and social benefits. This argument was widely accepted, but institutionalized in different ways. In the United States the task was assigned to a private company, American Telephone and Telegraph (AT&T), charged with providing a universal service that was both geographically comprehensive and priced at a level that made it accessible to all, and regulated (from 1934) by the Federal Communications Commission (FCC). In contrast, in Europe the task of providing universal service was assigned to state monopoly Post, Telegraph and Telephone (PTT) organizations owned and operated by the state. This same division between public enterprise and federally regulated private companies also characterized the institutionalization of broadcasting.

Unlike cinema seats or paperback books which are commodities purchased for personal consumption, broadcast services are public goods. They are available to anyone with suitable receiving equipment, and any number of people can listen or view at the same time without interfering with each other's enjoyment. This characteristic provided the technical rationale for the key tenet of universality. The institutional forms that broadcasting assumed in the early 1920s however were profoundly shaped by two contexts. Firstly, the British experience of managing strategic resources, such as timber in World War I, had convinced at least some economists that public corporations were the most appropriate way of

addressing the limited space in the radio spectrum available for broadcasting. Secondly, the social unrest that had followed the end of the War, the victory of the Bolsheviks in Russia, and the extension of the franchise to women for the first time led many commentators to see a public monopoly as the best way of securing responsible and rational participation in mass democracy in uncertain and volatile times. Accordingly, after careful deliberation, in 1926 the British government opted to transform the commercial monopoly initially given to the British Broadcasting Company (operated by a cartel of radio manufacturers) into a public service monopoly, the British Broadcasting Corporation, forbidden to take advertising, funded by a compulsory license fee on set ownership, and charged with providing informational and cultural resources for citizenship, as defined by political and cultural elites. In the United States, in contrast, radio was widely seen from the outset as a business opportunity. Its promise of widespread and instantaneous access to homes made it an attractive advertising medium in a context where a mass consumer system was expanding rapidly. Despite dissenting voices and a fierce rearguard action by educational and other public interest groups, broadcasting became primarily a privately owned advertising supported system, oriented to maximizing audiences by providing popular entertainment, with the FCC allocating (and revoking) broadcast licenses and instituting backstop regulation to ensure a minimum degree of access to air-time for minority viewpoints.

These contrasting models of broadcasting as public service and commercial enterprise, communication for citizenship and communication for consumption, provided the basic templates for many other countries, although a number eventually settled for a mixed broadcasting economy, with public and commercial sectors running in tandem.

Consolidation and Critique

Broadcasting and telecommunications were exceptions, however. The key organizations in the other major mass media sectors – the press, cinema, recorded music, and advertising – remained mostly privately owned and minimally regulated, consolidating the potential control that corporations could exercise over the organization of public knowledge and culture. Critical observers responded by reaffirming and extending the main themes of earlier commentaries. Some, like Upton Sinclair (1920) in his attack on the American commercial press, *The Brass Check*, returned to the potential abuses of owner and advertiser power. Others, notably Danielian in his 1939 study, *The AT&T*, turned their attention to the operation of power in conditions of regulated monopoly. In Britain, Klingender and Legg, observing the monopolistic tendencies in the country's cinema industry and the growing power of the Hollywood studios, produced the first detailed political economy of a major mass media sector, *The Money Behind the Screen* (1937). But the most comprehensive contribution to establishing a general political economy of media came from two German scholars, Theodore Adorno and Max Horkheimer, who were strongly influenced by Marx, and whose 1944 essay, 'The Culture Industry,' sketched out a general model of the possible relations between the increasing commodification and industrialization of cultural production and what they saw as the narrowing possibilities for creativity and critical expression in the public sphere.

Most of these early contributions came from commentators who worked either outside the universities or on the edges of academia. It was not until the expansion of the university system in the 1960s and the rapid development of communications and cultural studies as academic specialisms in their own right that the political economy of the mass media found a secure institutional base within the academy.

Political Economy and Cultural Analysis

This new security led to a significant growth in academic research, but tenured faculty did not enjoy a monopoly of insight; and commentators working outside the universities continued to make important interventions in debates. Although this renewed interest in the relations between culture and economy ranged widely, it tended to coalesce around several key strands.

Firstly, the rise of multimedia conglomerates with interests spanning a range of public communications sectors breathed new life into long-standing questions about the possible links between patterns of ownership, structures of corporate control, and the range and diversity of cultural production, and produced a significant volume of research charting the new configurations. Debates around the implications of these emerging structures also found an audience outside the academy through books like Ben Bagdikian's *The Media Monopoly* (2000).

Secondly, analysts attempted to refine the general idea of 'the cultural industries' by investigating the contrasting ways production processes were organized within major media sectors and tracing their implications for the range and forms of cultural activity. The contributions of French scholars led by Patrice Flichy (1980) and Bernard Miege et al. (1986) were particularly significant in establishing this line of research.

Thirdly, researchers returned to political economy's central concern with the constitution of complex democracies by way of Jurgen Habermas's influential idea of 'the public sphere' as a space of open debate situated between the state and capital and relatively independent of both. This led a number of critical analysts in Britain and Europe to reply to commentators calling for an enlarged market sector in television with a vigorous defence of public service broadcasting as the cornerstone of a mediated public sphere.

Fourthly, scholars moved beyond the issues raised by the changing conditions of national media to explore the recomposition of the emerging transnational communications system. Just as the last of the former colonial territories achieved political independence and emerged as autonomous nation states, critics led by Herert Schiller (1969) argued that they were being incorporated into a new imperial system, based not on the annexation of their territories but on the colonization of their cultures by the aggressive consumerism promoted by the major American media and entertainment corporations.

Fifth, encouraged by the rapid growth of the underground press, community radio, and a range of other alternative and oppositional media from the mid-1960s onward, critical

researchers began to explore the political economy of nonmainstream media.

These various strands of work attracted widespread criticism from cultural analysts working in other intellectual traditions who accused political economists of reducing cultural life to economic forces and denying the agency of audiences and consumers. This criticism is misplaced. Political economy does not deny that consumption may be marked by creativity, improvisation, and opposition but its core concern is with how the underlying dynamics of economic life shape communicative practice by allocating the material and symbolic resources required for action and how the resulting asymmetries in their control and distribution structure both the conditions of creativity in cultural production and the conditions of access and participation in cultural consumption. Audience may be active but they are also commodities traded between advertisers and commercial media.

Marketizing Media

As noted earlier, political economy is particularly concerned with the way that asymmetries in the distribution and control of core resources for cultural action impinge on the vitality of participatory democracy. In pursuing this argument, critical political analysts start from the material and cultural resources required for full citizenship. This leads them to evaluate the performance of public communications system in terms of their promotion of cultural rights-to information, knowledge, representation, and respect and their provision of a cultural commons hospitable to the negotiation of unities that incorporate diversity. This is in marked contrast to those economists and mainstream political economists who start from the conditions required to maximize market choices and address individuals as consumers of goods rather than as participants in a moral community.

Since 1980, propelled by a revival of neoliberal economic thinking the market has increasingly become the preferred mechanism for organizing public communicative activity and the touchstone for evaluating the performance of those cultural institutions that remain within the public sector. This general process of marketization (Murdock and Wasko, 2007) has four major dimensions:

1. *Privatization*. Media organizations that were formerly part of the public sector and supported by public money have been sold to private investors and converted into private enterprises. Examples include BT, Britain's former PTT and now one of the leading corporations in the national economy, and the former French public service television channel, TF1.
2. *Liberalization* involves opening markets that were previously dominated by one or two operators (monopolies and duopolies) to competition from new entrants. Examples include the liberalization of telecommunications in the United States with the breakup of AT&T and the ending of its historic monopoly, and the introduction of commercial cable and satellite television services into European broadcasting markets previously monopolized by state-funded public service channels.
3. *Regearing of the regulatory regimes* by shifting toward 'lighter touch' regulation that allows private companies more freedom of action in key areas such as corporate acquisitions and the amount and type of advertising carried, and removes or weakens established public interest requirements.
4. *Corporatization* involves reducing the real level of public subsidy and encouraging or impelling public institutions to raise more money from market-based activities, moving them closer to the strategies and rationales of the corporate sector. The BBC's decisions to maximize the commercial returns on its programming, to develop new initiatives with private sector partners, and to launch its own commercial enterprises, provide a good example of this process in action.

Taken together these intersecting processes of marketization have had three major effects on the ecology of public communications. First, they have consolidated and extended the economic power of the major multimedia corporations by opening up new fields for enterprises (Fitzgerald, 2011). Secondly, they have eroded the relative countervailing power of public institutions. Thirdly, they have progressively detached the core sectors of public communications from the project of providing everyone with the basic cultural resources required for full citizenship and moved them toward the satisfaction of plural consumer demands. As market segments have proliferated, the cultural commons has contracted.

Globalizations

The process of globalization is not confined to the major capitalist economies. With the collapse of the Soviet Union, the expansion of markets in the world's two most populous countries, China and India, and the almost universal embrace of market disciplines in the rest of the world, it has become the dynamic principle underlying economic globalization. This process has had contradictory consequences. Firstly, it has extended the geographical reach of the major western media conglomerates prompting a revival of the cultural imperialism thesis. Secondly, it has expanded opportunities for national entrepreneurs creating new forms of competition and collaboration between global, regional, and local companies. Thirdly, it has raised new questions about the relations between capital and the state in the cultural sphere, dramatized most forcefully by the increasing economic power of China and the endemic tensions between the 'party line and the bottom line' (Zhao, 2008).

Digitalizations

The present media systems is also being transformed by the fundamental technological shift, from analogue to digital communications systems, and the emergence of new spaces of expression and enterprise, led by the Internet. Four dimensions of this shift are of particular interest to political economy. First, the growing concentration of control over the Internet in the hands of established media majors and the new communications conglomerates, typified by Google, coupled with the centrality of advertising finance has revivified long-standing concerns around the impact of ownership and commercialization and the role of regulation. Secondly, the commercial appropriation of ideas and material provided by users, also the routine collection, processing, and the sale of their personal

information has prompted have renewed interest in the commodification of audience activity and the shifting relations between work and play. Thirdly, digitalization has major consequences for public cultural institutions such as museums, libraries, and public service broadcasters, furnishing opportunities to extend the range of materials and services they offer, and to forge new relations with their constituencies. Fourthly, the explosion of vernacular expression and horizontal peer-to-peer exchange on the Internet has revived interest in the dynamics and sustainability of non-market gift economics based on reciprocity and their possible role in creating a new public sphere of deliberation and participation capable of reinvigorating democratic ideals and processes.

Analyzing the shifting relations between the cultural economies of commodities, public goods and gifts, and the ways they are being shaped and reshaped by the intersecting forces of marketization, globalization, and digitalization not only presents the political economy of communications with a major challenge but also presents a major opportunity to reaffirm the continuing relevance and centrality of its core concern with the constitution of democratic life.

Abstract

Representation involves making something perceivable to an audience not in its physical presence. Inevitably partial, representation in the media requires framing, the selection and highlighting of aspects to stand for the whole. Scholars of media representation probe the combination of absences and presences in media texts, the meanings this total package likely conveys to audiences, and the ramifications of patterns in representation for power and belief in a society. Following a conceptual discussion, this article explores three major scholarly issues: how representations in the media reflect and affect the social status of group members such as women and blacks; how the representations might influence a mass audience's preferences in a particular election or policy dispute; and the ways media representations might influence elites and officials. The article suggests that media representations help define a society's culture, reflecting and reinforcing dominant cultural values and status hierarchies, yet also, at the margin, revealing and stimulating cultural change.

Representation involves making something perceivable to an audience that is not in its physical presence. Often the item represented – an idea, an ideology, an interest – possesses no tangible physical embodiment so representation means representing it in a new symbolic form or context. Other times a physical antecedent exists, such as a person, a widely recognized social group, an institution, or a place. Even these objects, when represented in the media, typically carry ideological or cultural meanings. There is now an extensive literature on media representations of social and political groups and institutions, and on their implications for the distribution of status, wealth, and power.

No representation is comprehensively accurate. All media representations inevitably omit some aspects of the item represented. Indeed in most cases only a tiny fragment of the actual idea, person, or group will be perceivable to the audience. Audiences may and often do fill in much of the absence themselves, drawing on their pre-existing mental theories or schemas. Studying representation means probing the combination of absences and presences, the meanings this total package is likely to convey to audiences, and the ramifications of these patterns of representation for power and belief in a society.

It is also vital to understand that there is no one-to-one correspondence between representation in the media text and the representation of the text and its signals as inferences drawn in the minds of audiences. The message that a communicator intentionally encodes in a media text may get decoded in ways that contradict or bear little relation to the communicator's purposes. Because representation involves both encoding and decoding, the conscious intentions of the communicator may have surprisingly little relevance to individuals' reactions and thus to the political and social impacts of media representation. This point is sometimes lost in popular and even academic studies of the media's influence, which frequently take individual media personnel to task for what analysts assume will be the effects of the representations. Vidmar and Rokeach (1974) provided a classic example of the slip between intentions and influence in their study of the popular American television program 'All in the Family.' To illustrate the absurdity of ethnic prejudice, Norman Lear, the show's creator, made its central character, Archie Bunker, a laughably ignorant, outspoken bigot. Yet despite the ridicule heaped upon Archie and his bigotry in most episodes, Vidmar and Rokeach revealed, the show merely reinforced viewers' predispositions. Far from changing their minds or even experiencing discomfort, prejudiced viewers saw Archie's tirades as vindication of their own sentiments.

Communication scholars studying media representation have typically done so to discern likely media influence. But cultural studies analysts and others working in the postmodern mode found surprising allies among those within the positivist and behavioralist traditions in stressing that individuals' interpretations of a given text vary so markedly that studying texts in isolation from their audiences produces flawed accounts of media representation. The major work of representation goes on within each thinking individual's brain rather than in the text, they say. Therefore, much of the scholarly focus in the 1990s shifted towards exploring the audience's interpretations rather than the media text by itself.

This article assumes that the representations in the text influence without determining individuals' sentiments. Beyond this, at the aggregate level, the pattern of representations in a society's mass media illustrate and help define its culture, reinforcing dominant cultural values yet also revealing and stimulating cultural change. These assumptions do not require a one-to-one correspondence between text and mind or text and culture, but do insist that the correlations are often significant. The conflict over just how significant – that is, how powerful media representations are – runs through media scholarship from its earliest days and continues in the most recent work. To cite ideal, polar types, some take the position that individuals make up their own minds, independently reconfiguring anything represented in the media to find meanings that suit their own experiences, knowledge, psychic needs, and goals. Others assert that in 'telling people what to think about,' the media can significantly and sometimes decisively influence an audience's attitudes and preferences. Between these two poles lies a diverse array of theorists who believe an audience's thinking is both influenced by and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95043-8

influences the representations that media transmit, with the degree of media impact depending on many environmental and individual differences.

One of the first major bodies of social scientific research on mass communication explored the representation of violence in movies and its impacts on youth. World War II spawned much research on propaganda – on media texts and their uses of symbols and language to generate potential shifts in mass attitudes. The next two decades saw a dry spell as scholars generalized from this and other early empirical research into media effects, concluding that any consequences of media representation were of minimal significance, limited largely to reinforcing existing predispositions. Advances in conceptualization and in analytical techniques challenged this stance and led to a renaissance in scholarship on media influence.

The more recent social scientific scholarship tends to run in two channels, one focusing on journalism and the news, the other on television and film entertainment (with occasional attention to magazines, radio, popular music, and novels). However, scholars toward the end of the century were increasingly recognizing the blurring of this always-problematic distinction between entertainment and news. Not only was news becoming more 'entertaining,' more shaped by strategies for audience appeal traditionally used by entertainment – in response to rising competition from commercial broadcasters, websites, print media, and other sources – but entertainment offerings on the US broadcast networks were becoming increasingly topical. A resulting hybrid dubbed 'infotainment' occupied increasing portions of the broadcast airwaves and of daily newspapers as well, in the US and elsewhere. As a result of this dissolution of once-distinct lines, an essay on media representation must not limit itself to the traditional news media, even though the bulk of social scientific research has probed the news.

Framing

Representation is always partial, always requires selection of aspects to stand for the whole (otherwise we would be speaking of presentation, not representation). Since framing is the process of selecting, highlighting, and suppressing, it is the means through which most media representation takes place. Framing has organized an increasing portion of the literature on media representation. Most of this research rests on the proposition that framing devices are worth studying because they affect (without necessarily determining) the audience's thoughts and perhaps actions. Framing can be defined as selecting aspects of a perceived reality and making them more salient in a communicating text, thereby promoting a particular problem definition, causal interpretation, moral evaluation, and/or treatment recommendation.

The classic experiments of Kahneman and Tversky show that framing the same basic event or problem differently can have marked effects on an audience's understanding of the item represented. For instance, Kahneman and Tversky (1984) gave subjects in one group a choice between a disease prevention program, A, that would 'save' 200 out of 600 people, and B, which would have a one-third probability that all 600 would be 'saved.' Then, using a matched group, Kahneman and Tversky reversed the frame so that option C meant '400 people will die' and option D offered a one-third probability that 'nobody will die.' Option C was identical to A, as was D to B, excepting only that A and B were framed in terms of 'saving' and C and D in terms of 'dying.' Yet in the first experimental group, 72% of subjects chose A, whereas only 22% in the second group chose the identical option C – presumably because C was framed to highlight death instead of lives saved.

Kahneman and Tversky's experiments typically involved small changes in wording bringing about significant changes in response (apparently because the participants in the experiments thought about the matter differently, focusing their minds on different aspects of it). Media studies tend to document far more global differences in framing, involving not just word choice but disparities in visual portrayals, aspects of the item emphasized, sources relied upon, people quoted, and more. If differences of a single word can cue markedly different responses, the multidimensional differences in media frames often demonstrated by scholars implicitly suggest considerable media influence.

For example, US media developed starkly different frames for two incidents in which civilian airliners were shot down by military forces, resulting in nearly 300 deaths each. In the first incident, the downing of a Korean Air Lines jet by the Soviet Union in 1983, adjectives and nouns, dramatic graphics, attributions of agency and other aspects of the text emphasized the suffering of the victims and the Soviets' moral guilt. This frame fit with then-president Ronald Reagan's political agenda of heightening Americans' distrust of the Soviet Union and polls showed that the overwhelming majority of Americans accepted Reagan's interpretation of the incident. By contrast, when US forces shot down an Iranian passenger jet in 1988, the media framed the event as a regrettable accident traceable to understandable human error and deficiencies in technology. Language eschewed moral judgments and the victims received scant attention. Here too large majorities of Americans in surveys accepted the Reagan administration's framing – this time exculpatory rather than condemnatory. Public acceptance of the way the media represented the incidents in turn had significant political and policy consequences (Entman, 1991).

Nonetheless, framing is far from all-powerful. William Gamson's studies of 'collective action frames' have shown how individuals, interpersonal discussion, and media frames interact. Studying issues including nuclear power and affirmative action, Gamson (1992) found that audience members take cues from news reports, but, depending on their individual thinking, group discussions, and the nature of the issue, can draw from the media-supplied frames new ways of understanding the phenomenon reported. For example, journalists did not construct the dominant news frames and thus the representation of nuclear power to stimulate antinuclear activism. Nonetheless, audience members gathered by Gamson in focus groups were sometimes able through collective deliberation to reframe the issue in a manner that might have moved some to action.

An understanding of the bidirectional influence of media representations and audience thinking immediately cautions against inferring any single meaning or effect from a particular media text. The same text can represent or 'mean' different things to different people in different circumstances – including

different historical periods. Thus the words 'racial equality' represented one concept during the 1950s and 1960s – equal treatment and equal rights under the law for black Americans. More recently, the words appear to connote something quite different for many at least in the US, something akin to radical redistribution of income, wealth, and opportunity from the majority Whites to minority groups.

Despite these cautions, the bulk of research on media representations appears to assume that one basic interpretation often – though certainly not always – dominates, at least among the members of any specific culture at a particular time. In fact, one definition of a culture might be sharing cognitive habits and schematic mental linkages that promote similar responses to an attitude object among the individuals who constitute its membership. The (typically implicit) assumption that representations in the media have a 'preferred' or 'privileged' interpretation or meaning in a given culture structures much of the remaining research reviewed here.

To generalize broadly (an inevitability in a literature synthesis covering such a wide area of research), media research explores three aspects of representation corresponding to three kinds of effects (often presumed rather than empirically demonstrated): the ways representation reflects and affects the general social status of group members such as women and blacks; the ways media representations might affect a mass audience's political preferences in a particular dispute, say in an election or a debate over legislative proposals; and the ways media representations might influence political elites and government officials.

Status Reinforcement or Enhancement

Students of media representation frequently examine depictions of groups and how they might reflect, reinforce, or challenge existing status hierarchies. For this purpose, a wide range of human classifications has been invoked, from race and ethnicity to gender, sexual orientation, age, and language groupings.

In this research tradition a major thrust focuses on ethnic groups. For the most part, the research suggests that media images reflect and reinforce dominant status judgments. That is, in framing activities involving members of lower-status groups, the media highlight aspects likely to reinforce perceptions among the dominant group's members of their difference from and superiority to outgroups. Representations tend to carry explicit or implicit judgments of the outgroups on dimensions of morality, intellectual capacity, industriousness, lawfulness, and other valued traits. But because media images are in constant flux and often contain contradictory elements, they also provide cognitive resources for challenges to status markers.

Of particular concern to many researchers has been a pattern whereby the media link crime and dangerous deviance to people of color and especially black males (Entman and Rojecki, 2000). Experimental studies repeatedly have suggested that these representations engender cognitive and emotional effects on white audiences that affect the exercise and distribution of power – in this case heightening support for punitive prison sentences or diminishing support for white candidates when political advertisements associate them with black criminality (Gilliam and Iyengar, 2000).

Studies of depictions of 'foreigners,' by which is usually meant nations and peoples other than those with white, European ancestry, also fit into this mode. For example, news media coverage of humanitarian crises in Africa, though typically sympathetic to those suffering, manages to endorse racial status hierarchies that place whites at the peak of the pyramid. Thus, Western news media made Bosnian whites appear in a variety of ways more human, more worthy of help, than news of the genocide going on simultaneously in Rwanda (Myers et al., 1996). The same appears true in entertainment. For example, a study of Brazilian TV star Xuxa suggests that her celebrity (and earnings) derived largely from her conformity to North American and North European ideals of blonde sexuality and beauty (Simpson, 1998) – even in an ethnically heterogeneous country priding itself on multiracial tolerance. This white cultural preference reflects continuity with a long history in which European and US mass media implicitly derogated black people and valorized whites and the qualities typically associated with whiteness.

In a similar vein, gender representations in the media are found to register cultural change on some dimensions but to endorse traditional patriarchy and gender roles on others. Thus we see women actors portraying business executives in advertisements, and single women living happy lives without obsessing over men. But, although women's sports now receive media attention that gives the lie to assumptions that women are inevitably passive, gentle, timid and the like, closer study suggests the continued impact of gender stereotypes and a preference for males. For instance, research on portrayal of women's sports in Sweden shows that female athletes and their pursuits are implicitly derogated in comparison to males – over 90% of the time devoted to sports in a sample of Swedish television programming covered male athletics (Koivula, 1999). Beyond this, women still drive the plot in far fewer movies and television programs than men, and still serve as sex objects more often than males. Women's sexuality indeed appears more than ever to be pictured in unrealizable body types that have been linked to an increase in anorexia and other eating disorders. Thus a study of Australian adolescent girls finds a strong influence of media consumption on tendencies to aspire toward unhealthily thin body types, findings replicated in other countries (Wertheim et al., 1997). The studies of female body images typically find that many audience members absorb the preferred meanings and integrate them into their own self-images. These findings challenge any claim that mass audiences always engage in subversive readings of media representations.

On the other hand, Fiske (1992) argues that despite the traditional patriarchal and commercial values inherent in the pop star Madonna's representations of femininity, young women frequently found reinforcement for nontraditional roles and values through their own counter-readings of Madonna's music and videos. Certainly the growth in sheer numerical representation of blacks, women, and other traditionally less-empowered groups in nontraditional roles in Hollywood movies, music videos, and television dramas has both reflected and reinforced a degree of movement toward a more egalitarian status hierarchy.

Looking at status on the dimension of sexual orientation, Joshua Gamson (1999) argues that although the confessional talk shows that became popular in the US during the 1990s, such as 'Jerry Springer' and 'Maury Povich,' seem on the surface to belittle anyone who deviates from the middle class, heterosexual norm, the programs actually offer a more complex ideological brew. Sometimes the shows construct morality plays that censure gay, lesbian, or transsexual guests, but other times the intolerant snob, ivory tower expert, or sexual bigot assumes the role of villain. Arguably, says Gamson, gays and others living outside the bounds of dominant cultural values find a more welcoming home for self-representation in the 'trash' talk shows than in the rest of the mainstream media. In this sense, tabloid TV, driven as it may be by crass commercial goals, debasing as it may appear to public discourse, may open up new space in the public sphere for persons, ideas, and values previously denied much representation in either entertainment or news.

Media Representation and Political and Policy Disputes

Moving along a continuum from media representation's impacts on mass publics to impacts on the political linkages between them and elites, we turn now to representation in news coverage of current policy and political contests. Here too the research suggests media most often operate to reinforce structures of power that privilege native born white men.

Thus, for example, female political candidates have been shown to face disadvantages against male candidates. They often receive less news coverage than males, and the news agenda seems to follow male candidates' issue choices most closely. On the other hand, women candidates may benefit from being associated with positive sex-role stereotypes (Kahn, 1994). With a black candidate in the race, campaign news tends to emphasize candidates' racial identities and to frame elections as contingent on bloc voting by whites and blacks (Reeves, 1997), and this demonstrably handicaps African American candidates.

The representation of nonelectoral dissent against powerful institutions has also received careful scrutiny. Research reveals a tendency for media to accept moderate, polite dissidents who work within the system and make conventional, incremental demands, but to slant decisively against groups that seek more radical objectives, undermining their legitimacy with the public and thus reducing the need for elites to respond positively to their goals (Gitlin, 1980).

A subject of much dispute in the US has been representations of parties and candidates in national elections, with some scholars alleging systematic biases favoring one party and others denying these exist. Additional studies explore other kinds of bias than partisanship, suggesting the possible impacts on voting turnout or civic orientations. For example, US journalists increasingly infused their representations of candidates and campaigns with cynicism during the latter decades of the twentieth century, and this appeared to encourage political distrust and withdrawal among audiences.

Alongside such research there also arose theoretical essays that challenged the notion of bias by questioning the legitimacy of its presumed opposite, 'objectivity.' The notion that media can represent people and events in comprehensively accurate and politically neutral ways appears to be a powerful professional ideal for journalists. Nonetheless, scholarship almost universally denies the proposition and asserts that in the course of manufacturing the news, individuals and media institutions must inevitably embed certain kinds of biases (that is, preferred meanings or politically consequential omissions) into their reports. Although US studies, at least, fail to uncover systematic partisan biases, other forms of bias have been analyzed extensively, such as a bias for reporting political conflict over agreement, and political process over policy substance.

Elite Impacts

The newest and least developed area of research examines the impacts of media representations on elites. In democratic systems, elites are under pressure to respond to 'public opinion,' but it turns out they have few reliable ways to discover what it is on any given issue under debate in the legislature. Surveys are only sporadically useful in trying to gauge the sentiments of a legislator's constituency. Thus, media representations of 'public opinion' to officials become highly consequential. Political elites can only respond to the public thinking that they perceive, and they get much of their data on this from media reports. Moreover, these reports can become self-fulfilling, because they also may influence the public itself. In this view the media become a representative vehicle in the more specific political sense of forging ties (imperfect to be sure) between mass public and elites, by representing 'public opinion' to elites – by making abstractions, here the public's purported preferences and priorities, perceivable so elites can act on that information.

The process becomes even more complicated because elites contending to control the outcome of policy disputes frequently resort to manipulating the media. This may help create impressions of public support or opposition, impressions that augment or derail the momentum of policy proposals. Yet another twist is that media representations have themselves become a contentious political issue – an issue that is itself subject to biased representation. In the US, surveys clearly reveal that increasing majorities over the last few election cycles of the twentieth century came to believe that the media exhibit a liberal bias (Watts et al., 1999). Yet, as noted earlier, empirical studies fail to demonstrate a systematic ideological slant in the news. The public's perception of bias appears rooted in news coverage of news-making itself, and in stories quoting politicians, party elites, and think tank intellectuals who have made purported media bias a theme of their speeches and writings. Watts et al., (1999: p. 144) find that in campaign coverage, 'conservative candidates, party officials, and supporters have dominated the discourse with allegations of liberally slanted news content.' The claims of left-leaning bias 'overwhelmingly' outnumber those of conservative bias – in the 1996 campaign by 91 to 9%. Thus there appears to have been a bias in the media's representation of points of view about the media's ideological representations – ironically, conservatives may have succeeded in biasing the US media's representations of media bias. The topic of media representation has itself entered the arena of political contestation and strategy,

although the effects on the media, or on power in politics and society, are not yet clear.

Conclusion

The spread of new media and many new sources of mediated information and images raises questions about the nature of the system of media representation and scholars' ability to generalize about it. The Internet is freely open to almost any representation one might imagine, and its images are readily and simultaneously available to audiences around the globe. The impact of this wider circulation of more diverse images and words could be profound, disrupting the past ability of mainstream media representations to set agendas and shape dominant interpretations. On the one hand, the Internet puts more potential power over individuals' internal representations and thoughts into the hands of each individual, at least those who devote sufficient time to surfing the Web and seeking new views. The seemingly significant media effects discussed here – on group status, on the outcome of elections and other disputes, or on elite behavior – could diminish. On the other hand, this very decline of a homogenizing mass media has some scholars worried that the public sphere will dissipate, only to be replaced by a cacophonous set of specialized subpublics that communicate not with each other but only within their own boundaries. In the future, the very notion of common culture and nationhood forged by public attention to common media of mass communication could come under pressure.

Mass Society: History of the Concept

Abstract

The history of the notion and theory of mass society is explored, from its ancient roots in Greek and Roman political thought about 'the many' and 'the few,' until modern times. Theories about the plebs, demagoguery and revolutionary crowds in thinkers such as Plato, Cicero and Hobbes are shown to bear upon later conceptions. The modern idea of a leveled, homogenous society developed by Tocqueville in the nineteenth century, combined with the fears about 'the masses' expressed both by 'crowd psychologists' (Le Bon, Freud) and conservative writers, are seen as the precursors of the contemporary mass society conception, as it appears in its mature form in Ortega's *Revolt of the Masses* (who introduced the notion of 'mass man') and in the works of Mannheim, who introduced the expression 'mass society.' The diverse ramifications of the mass society conception into the contemporary theories of 'mass culture,' 'mass politics,' the 'homogenization' of society, 'mass comsumption,' and the 'depersonalization' of modern human beings (Riesman's notion of the 'outer-directed personality,' Marcuse's 'one-dimensional man') and other, closely-related, interpretations are also analyzed. The widespread persistence of the mass society conception in contemporary thought, often subsumed into other interpretations of modernity, is explored.

'Mass society' is a notion central to the assumption that modern, advanced societies possess the following features: a growing internal homogeneity, a combination of elite and bureaucratic control over the majority of the population (the so-called 'masses'), a specific kind of predominant culture ('mass culture,' linked to the 'mass media'), and an illiberal form of politics ('mass politics' and 'mass parties'). They are also said to reflect a new stage in the development of the industrial economy through 'mass production' and 'mass consumption.' 'Mass society' frequently assumes that, in such advanced societies, a certain type of human personality, the so-called 'mass man,' is proliferating and becoming omnipresent. This mass man is thought to embody the mindless uniformity of social conditions and moral attitudes.

The Twentieth Century Origin of the Concept

In its contemporary sense, the term 'mass society' (*Massengesellschaft*) was coined by Karl Mannheim in Germany in 1935. However, the first general description of a mass society, as it was to emerge in the social sciences and in the sphere of social ideas in the post-World War II period, was first put forward by the philosopher José Ortega in 1929, in his influential essay *The Revolt of the Masses*. Ortega also launched the expression 'mass man' (*hombre masa* in Spanish), a notion intimately related to that of mass society. These contributions from Mannheim and Ortega were preceded by other notions, such as 'mass production,' but most of the 'mass society' expressions appeared after these had become accepted terms. Of these, 'mass politics,' 'mass culture,' 'massification' – a translation of the German *Vermassung* – and 'mass consumption' are the best known. Still others, which did not always include the qualifying word 'mass,' were often used as synonyms of mass society or equivalents for it: for example, David Riesman's 'lonely crowd' and his concept of 'outer directed personality' which largely overlaps with standard descriptions of 'mass man.'

Despite the twentieth century origin of the expression (as well as of the set of concepts to which it soon became inextricably linked), both the notion of mass society and the arguments (or theories) behind it are much older. Thus the idea of a mass society contains some conceptions (and prejudices) about the nature of human society which are truly ancient, while some of the most elaborate interpretations of the world it claims to describe hark back to classical nineteenth century thinkers, such as Alexis de Tocqueville, to several pre-World War I philosophers and sociologists, and to contributions made by the so-called 'crowd psychologists' of the same period.

The Classical Origins of The 'Mass Society' Conception

The Ancient Roots of the Concept

The set of problems destined to occupy the minds of modern theorists of mass society are clearly related to those which inspired the ideas of the earliest conservative critics of democracy. The latter were concerned that the extension of citizenship and equality to the majority of the people making up the body politic might also entail the access of common, ignorant, vulgar, and politically and legally untrained men to public office. Public office, they thought, ought to be the preserve of legally trained, well educated, and wise citizens. Although Plato in the *Republic* put forward a scheme for the selection of the ablest and best citizens for high office (both women and men) on an egalitarian basis – through equal educational opportunities for all – most conservative observers at the time feared that all actual democracies would easily degenerate into mob rule.

Later, some historians, such as the Greek Polybius who lived under Roman rule, suggested that humankind underwent a cyclical historical process and that periods of democracy

quickly and inevitably degenerated into what he called 'ochlocracy,' that is, mob rule and social chaos. Saint Augustine for his part was probably the first to use the word 'mass' for the majority of the people, by referring to those incapable of saving their own souls as the *massa damnata*. He explicitly distinguished an elite – those to be saved, to use his Christian term – and the rest, the undistinguished, united in their failure to free themselves from sin.

Thus the association between crowd behavior, unruly assemblies, emotional and irrational meetings, on the one hand, and the general breakdown of social order, on the other, appeared at the earliest period in the history of Western political thought. Similarly the people's supposedly innate vulgarity and lack of moral fiber was contrasted with the refinement, creativity, courage and distinction, and individuality of the select and responsible few. The dangers of demagoguery – irresponsible leadership of the *plebs* or populace, often coming from isolated members of the elite – were also mentioned by numerous political thinkers during the classical period – from Aristotle to Cicero – in terms not altogether different from those used by some representatives of the modern theory of mass politics.

Classical Underpinnings from Hobbes to Tocqueville

Neither medieval nor Renaissance thought permitted much further development of the seminal ideas about the majority and its relationship to privileged and powerful minorities, much less the rise of a conception of the social world in which egalitarianism was seen as posing a danger to freedom and a source of human bondage. The social upheaval of the seventeenth century, however, inspired Thomas Hobbes in *Leviathan* and especially in his reflections on the disturbances of the English Civil War, the *Behemoth*, to return to ancient themes about the pernicious results of upsetting the hierarchical order of society by demagoguery and mob rule. Political obedience to the sovereign by the many might entail strains and injustice, but anarchy led to much greater evils, both for the body politic and for the preservation of civilization and human life. In *Leviathan*, by simplifying the structure of a viable body politic and making it quite homogenous under the power of a single sovereign, Hobbes pointed to some of the features and problems of government to which theorists of mass politics (i.e., of the political dimension of mass societies) would turn their attention in the twentieth century.

In the history of the concept of mass society, it is worth noting that neither the first fully-fledged interpretation of such phenomenon (Ortega, 1929) nor the first general presentation of anything approaching the notion of a mass society, Alexis de Tocqueville's *Democracy in America* actually used the expression itself. Although Tocqueville's study (1835 and 1840) did not describe the rise of a mass society, his analysis of the dynamics of a liberal, individualistic and democratic polity, clearly pointed out the trends (both manifest and 'subterranean,' to use his characteristic expression) that would eventually lead to it: thus the pressure of a growing 'equality of conditions' in the modern world would make people more similar to each other and therefore erase the distinctions between would-be unique individuals. The powerful ideology of egalitarianism would also have similar repercussions: concessions to majority wishes made by politicians would produce a more mediocre kind of democracy; conformity, rather than orderly dissent, would undermine the vitality of the new culture of the age; hedonism, rather than striving for higher forms of culture and ideals, would inspire the behavior of a selfish citizenry. In a word, a world of lonely, aimless, vulgar pleasure-seeking and disoriented citizens could eventually – though not necessarily – arise from the general trends to be perceived in the age of democracy.

Conservatism and 'Fear of the Masses'

Tocqueville's contribution is important because, for the first time, and almost explicitly, he made a distinction between crowd and mob behavior, on the one hand, and the increasingly uniform structure of advanced democratic societies, on the other. Nevertheless, in the decades that followed, observers tended to concentrate on crowd and mass behavior rather more than on the homogenization (or 'massification' as it later was called) of the entire society.

This interest in crowd behavior came, almost entirely, from the conservative quarter. In their eyes, the progress of democracy during the nineteenth century, especially in the great urban settings of the West, would bring many people – i.e., particularly industrial workers – into the streets to confront governments or to defy public order with demonstrations, strikes, and public meetings. An entire series of observers – mostly the so-called crowd psychologists – produced studies and speculated about the irrational, emotional, and manipulable behavior of the masses. Gustave Le Bon's *The Psychology of Crowds* (1896) is the best-known, though many other similar studies were produced, especially in Italy and England. A best-seller for its time, Le Bon's study brought the concept a step closer to the identification of crowd behavior with the general structure of society, already described by some at the time as 'the age of the masses.' A later essay by Ortega bears a title that still refers to the 'masses' rather than to an 'age' or 'society.' Meanwhile Oswald Spengler's *Decline of the West* ends with a somber and catastrophic view of the future of civilization precisely in terms of an 'age of the masses,' the 'barbarians from below.' For his part, Sigmund Freud wrote one of his most significant studies by developing critically some of Le Bon's ideas and intimated, like Le Bon and Spengler, that the future would belong to the rising masses and their dangerous manipulators. The masses were, by definition, incapable of rational and analytical thought and were also undemocratic in every way.

An alternative, democratic view, of the majority had difficulty emerging. At a given moment, anarchist and socialist thinkers began to accept the notion of 'the masses' in order to refer to the people at large (industrial and peasant workers together) in an entirely different vein to that of conservatives. Yet, with the rise of Bolshevism and, later, Stalinism, the 'masses' came to refer abstractly to a given population as controlled by the single party (the 'vanguard of the proletariat') and its 'cadres.' As such, the 'masses' were only assigned a subordinate role of acquiescence and obedience to the monopolistic party, instead of the autonomy characteristic of the people making up a truly free civil society. It cannot be said that, during the period of (Stalinist) Communist

predominance in large parts of the world (1917–89), observers within the narrow bounds of the official Marxist–Leninist ideology showed any confidence on the 'masses.' Thus, paradoxically, their views coincided with the pessimistic liberals' view of the same period.

Some Marxists or Neo-Marxists would eventually come to accept the term 'mass society,' which they applied mostly to advanced capitalist and 'imperialist' countries. Nevertheless, Western Marxists who escaped the discipline of their Stalinist counterparts often incorporated the concept of mass society to their analyses, as we shall presently see.

The Rise of the Modern Theory of Mass Society

Ortega and Mannheim

As pointed out above, the 'standard' interpretation of the modern world in terms of a mass society found in Ortega's *The Revolt of the Masses* represented the first general synthesis. His essay also included a number of original ideas (e.g., specialism as a form of 'barbarism,' or the notion that 'mass man' is not necessarily linked to the lower classes or to the proletariat). The anxieties and preoccupations of liberals (Tocqueville, John Stuart Mill), philosophers of civilization's decline (Spengler, Burckhardt), crowd and mass psychologists (Le Bon, Freud) elegantly and forcefully converged with Ortega's considerations but did not use the expression. Mannheim's notion of 'society of the masses,' more easily translated into 'mass society,' completed Ortega's vision, with his greater insistence on the bureaucratic and industrial structure of such universe. This was developed in his 1935 *Mensch and Gesellschaft im Zeitalter des Umbaus* (*Man and Society in the Age of Reconstruction* 1940). Mannheim, less conservative than Ortega, put forward possible solutions in a reformist, social democratic spirit.

Translated into English by Edward Shils – himself later a critical analyst of the notion – Mannheim's essay opened the way for the widespread use of the expression 'mass society' in the English-speaking world. In Spanish, many writers retained the plural (*sociedad de masas*), but this has not always been the case in other languages, such as French (*société de masse*) or Italian (*società di massa*; also, for mass politics, *regime di massa*; while Ortega's *hombre masa* was translated into Italian as *uomo di massa*).

Predominance and Expansion of the Mass Society Conception

As Daniel Bell was to point out in his *The End of Ideology* (1960), the mass society conception of advanced societies had become the predominant general vision of the world at the time amongst critics and thoughtful observers, save for the then widespread Marxist views about capitalism and its future. It remained so for a long time, although ramifications, schools of thought, and rival interpretations would also appear. This is not the place for a description nor a classification of such interpretations, however, we should mention that, alongside more conservative (in some cases, overtly pessimistic) views about the rise of a mass society in the framework of Western industrial advanced societies, there emerged some observers who embraced the notion from a left-wing or radical stance. C. W. Mills' attacks against the supposed degeneration of American society and democracy in his two studies *White Collar* (1951) and *The Power Elite* (1956) were typically made from a libertarian position against the development of a mass society on American soil (as a consequence of mass marketing, political manipulation, the undemocratic elite control over the citizenry by a 'military-industrial complex,' etc.)

Likewise, the widely influential neo-Marxist Frankfurt School, on both sides of the Atlantic, embraced the mass society interpretation and had a vast influence upon a wide educated public. Some of its products (*see* Adorno's *The Authoritarian Personality* (1950), which included a re-working of the mass man notion) were significant contributions in terms of social research; other studies, such as Horkheimer and Adorno's 1944 *Dialectic of Enlightenment* (English translation 1972) included a relatively sophisticated 'hegelianization' of the mass society theory. Yet others from the same school – e.g., Marcuse's *One-dimensional Man*, 1964 – popularized the notions of mass society and mass man for a large and quite anxious audience with less philosophical rigor.

More significant perhaps than any division of the notion and theory of mass society into a conservative and a radical version (from the early 1950s to the mid-1970s, by which time it had become truly dominant) was the development of 'specialized' branches of the conception. Two stood out. Firstly, the study of mass politics (further divided into speculations and research on totalitarian mass politics, and the study of pluralistic and democratic mass politics and parties). Secondly, considerable interest was aroused by what Shils had called 'the culture of mass society' (1975a, 1975b). Mass culture and media studies, sociological or otherwise as well as philosophical essays, proliferated and soon became a highly developed field of research and analysis. Most of the debates about the nature and dynamics of mass society took place (or often, raged) within this new field.

Accommodation and Persistence of the Concept

The successful emergence of other general concepts for referring to advanced societies in the most general terms (for instance 'post-industrial societies') either relegated or, in some cases, even drove out the use of the term 'mass society' from its frequent use by the mid-1970s. It did not disappear, however. The mass society conception was anything but a fashion, as its credentials in social philosophy, political theory, and the rigorous critique of civilization demonstrate. The predominant tendency, from the 1980s till the first years of the twenty-first century has seen the mass society notion finding accommodation within a number of other general descriptive concepts (and corresponding interpretations). Thus, along with such concepts as 'post-industrial societies,' we find 'post-capitalist' societies, 'corporate' societies, 'consumer' societies, 'information' societies, and several others.

These expressions are not mutually exclusive. Rather, they refer to different facets or dimensions of the same highly complex phenomenon. To give one example, the widespread interest in the development of corporatism, neocorporatism, and the so-called 'corporate societies' in the 1970s and 1980s demonstrated that theories and interpretations produced by students of these phenomena were often highly compatible

with the mass society theory. The latter's emphasis on administrative control, the rise of large transnational corporations, and anonymous social forces seemed to complement theories of corporatism.

The situation at the turn of the twenty-first century seems to indicate a certain decline, although a number of examples can be produced to demonstrate its persistence. Of all its several branches, the concept, research field, and theories of mass culture and the mass media have not lost – the contrary seems to be the case – any ground at all, either in the West or elsewhere.

More recent general interpretations, notoriously the 'globalization' literature, are not only compatible with the classical tenets of the mass society interpretation but are partly, it can be easily claimed, extensions of it. The notion of mass society always included a view of the expansion, interdependence, and general globalization of the supposed mass characteristics of late industrial Western civilization. The idea of world convergence of mass societies was explicitly built into it.

Abstract

Around the world, many populations are affected by mass trauma events such as natural disasters, wars, or terrorist attacks. Such large-scale events threaten the mental health of adults and children. The major mental health consequences of mass trauma are high prevalence rates of post-traumatic stress disorder and depression. For children, a broad range of maladaptation may result from the exposure to mass trauma events. Research from different such catastrophes has identified risk and resilience factors as well as intervention and prevention programs that meet the mental health needs of the affected populations.

Mass Trauma as a Global Phenomenon

Mass trauma refers to extremely adverse events and conditions that affect the well-being and mental health of large groups or even of whole populations. This relatively new concept allows summarizing and comparing findings on the psychological consequences of large-scale man-made and natural disasters such as wars, terrorist attacks, earthquakes, and floods. For example, in the last two decades, different research groups have gained considerable knowledge about risk factors for psychological disorders of adults and impaired development of children who live in a war-torn country such as Liberia (Johnson et al., 2008), survived the 2004 tsunami disaster in Asia (Neuner et al., 2006), or were affected by the 9/11 terror attack in the US (e.g., Perlman et al., 2011). The goal of mass trauma research is to identify common pathological reactions to such events and to identify risk factors and mechanisms that lead to mental health impairment. In addition, mass trauma research aims to develop and test programs for the prevention of dysfunctional development and the treatment of psychological disorders that result from the events.

While each catastrophe can be perceived as a regional event, a comprehensive understanding of mass trauma phenomena requires the analysis of differences and commonalities of reactions to extreme adversities across the world. Typically, mass trauma events are global phenomena as they raise international attention and assistance and are influenced by international processes such as the world trade of resources or extreme weather events associated with climate change. Low- as well as high-income countries of all continents have been equally affected by natural disasters such as floods or bush fires during the last decade. However, by far the highest number of casualties occurred in low-resource countries, while the highest material damage was caused in high-income countries (International Federation of Red Cross and Red Crescent Societies, 2013). At the same time, the 24 wars and 12 armed conflicts that took place in 2012 were restricted to low- and middle-income countries in the Middle East, Africa, and Asia. Still, most of these conflicts were associated with global economic or security interests. The term mass trauma also gives consideration to the fact that different types of catastrophes often occur simultaneously. For example, the tsunami disaster has affected different war-torn countries in Asia and terrorist attacks commonly occur during armed conflicts.

Psychological Consequences of Mass Trauma Events in Adults

Mass trauma events typically involve the destruction of the existential basis of a large number of the affected families. Whole populations may be forced to flee from their homes, which involves the destruction of social networks and roles. Life after a disaster or during a war involves states of continuous insecurity and dependency. Mass trauma events threaten the subsidence and survival of many people at once. While all of these different components of adversities present extreme stressors for the affected individuals, research on natural disasters as well as on wars has revealed that the exposure to events that involve a direct threat to the life and limb (like witnessing other people dying or experiencing an attack on a village) is the most detrimental aspect of mass trauma (Norris et al., 2002; Steel et al., 2009). Such events are referred to as potentially traumatic events as they can cause post-traumatic stress disorder (PTSD), which is, next to depression, the most common psychological disorder in the aftermath of a mass trauma event. PTSD is characterized by persistent intrusive memories of the traumatic event that keep recurring in the form of vivid images, thoughts, or nightmares, as well as avoidance of reminders of the event and a general state of hyperarousal and anxiety. Different studies have found a wide range of prevalence rates of PTSD following a disaster, and it is likely that methodological limitations including inadequate sampling and assessment explain much of the variance across studies (Steel et al., 2009). Sound studies have found PTSD and major depressive disorder in up to one-third of highly exposed survivors of natural disasters (North and Pfefferbaum, 2013) and up to almost one-half of survivors of war (e.g., Johnson et al., 2008; Karunakara et al., 2004), while far smaller rates of psychopathology were found for the typically less severely exposed populations living in high-income countries (Perlman et al., 2011).

As noted above, the most consistent and strongest risk factor for a trauma-related disorder is the amount of exposure to potentially traumatic events. In the context of mass trauma, several studies have identified a linear dose–effect relationship between traumatic events and probability of PTSD (e.g., Neuner et al., 2004). Next to the direct exposure to potentially traumatic events, different studies have identified a range of other risk factors for a pathological mass trauma reaction, including female gender, preexisting psychopathology, lacking

social support, and secondary adversities resulting from the event such as loss of property, poverty, and an increase of community crimes and threats (Norris, 2005; North and Pfefferbaum, 2013). Although spontaneous recovery from initial trauma reactions is common, longitudinal studies of disaster victims (e.g., Zhang et al., 2013) indicate a chronic course of PTSD in about one-half of those who had developed PTSD.

Psychological Consequences of Mass Trauma in Children and Adolescents

Children and adolescents belong to the most vulnerable groups in the context of mass trauma. Surveys with children growing up in war-torn areas have found prevalence rates up to 75% for PTSD (Catani et al., 2008; Thabet and Vostanis, 2000) and rates of major depression ranging up to 30% (e.g., Thabet et al., 2004). Natural disasters seem to have a similarly detrimental effect on the mental health of children (Neria et al., 2008; Weems et al., 2007). After the Asian tsunami in 2004, studies with affected children in Thailand and Sri Lanka reported high prevalence rates of PTSD, major depression, and suicidal ideation (Neuner et al., 2006; Wickrama and Kaspar, 2007).

Although the vast majority of data on the psychological impact of children's exposure to natural disasters origin from developed countries (Norris et al., 2002), such disasters typically have a much stronger impact on children's development and adjustment in low-income countries. Mass trauma events in low-resource countries are often associated with additional adverse events and conditions such as armed conflict, community and family violence, extreme poverty, and a lack of resources for health provisioning, or even the co-occurrence of mass adversities. For example, the 2004 tsunami catastrophe severely affected regions in Sri Lanka that suffered from an ongoing civil war (Catani et al., 2008). Children are particularly sensitive for the accumulation of stressors that occur in such contexts, and the detrimental developmental effects are not restricted to specific mental health diagnoses such as PTSD and depression. A broader and multifaceted set of outcomes needs to be taken into account when studying children affected by mass trauma. For example, unspecific internalizing as well as externalizing behavior problems have been associated with exposure to natural disasters as well as to war and conflict (Betancourt et al., 2014; McLaughlin et al., 2009).

A Risk-and-Protection Perspective on Children's Psychological Well-Being and Functioning in the Aftermath of Disaster

Many earlier studies and reviews on the effect of extreme adversity presented dose–response gradients to illustrate the detrimental impact of the accumulation traumas on children's psychological well-being. In fact, across diverse countries and disaster types, the severity and frequency of exposure to disaster-related traumatic events was one of the main predictors of psychopathology. For instance, a study with survivors of the Hurricane Mitch found that the level of the Hurricane impact was the strongest predictor of PTSD symptoms in adolescents (Goenjian et al., 2001). In war-torn populations, a linear relationship between exposure and trauma-related disorders has been confirmed in several studies with children exposed to mass trauma (Catani et al., 2008).

However, recent observations indicate that the mere assumption of a direct causal association between mass disaster and trauma-related impairment may be oversimplified. Beyond the individual level of analysis, and following Bronfenbrenner's bioecological system theory (Bronfenbrenner, 1979), it is likely that disaster-related trauma does not affect only isolated individuals but also communities and families. Impairments in family and community functioning may, in turn, impair child adaptation and development through secondary adversities such as parental loss, poverty, homelessness, and community and family violence (Pynoos et al., 1999). In line with this thinking, studies in postconflict settings have revealed elevated levels of family violence against children and adolescents (Catani et al., 2008; Saile et al., 2014). In addition, war and co-occurring family violence have unique effects on symptoms of PTSD as well as on child adaptation (Catani et al., 2010). These findings indicate that it is important to consider the multiplicity of adversities as moderators of impairment (Panter-Brick et al., 2011). Furthermore, a developmental mass trauma perspective needs to identify potentially protective factors within a risk-and-resilience framework (Betancourt and Khan, 2008; Masten and Narayan, 2012). Protective factors or assets consist of individual characteristics of the child's developing biosystem but may also be found on the family as well as community level or in the societal and cultural context (Norris and Stevens, 2007). Given the high impact of the parent–child relationship, the family might not only act as stressor in case of family violence but also foster children's resilience through care and warmth (Masten and Narayan, 2012). Low parental care and high levels of authoritarian and intrusive parenting (overprotection) have been associated with poor psychological adjustment (Enns et al., 2002). There is initial evidence that this relationship might also be valid in war-torn populations on top of the mass trauma context. Betancourt and coworkers (Betancourt et al., 2013) found a correlation between low parental care and high rates of internalizing behavior problems in Sierra Leonean children exposed to the war.

Apart from risk and protective factors related to the family system, potential moderators on other ecological levels might potentiate or buffer the effects of mass trauma on children's mental health. With respect to the individual level, age and gender of the child, specific disabilities, and differences in personality, e.g., self-control or coping skills have been discussed (for a review, see Masten and Narayan, 2012). In recent years, the study of biological variables has become a major research focus, and genetic moderators have been discussed that might potentiate the developmental risk in the context of trauma and disaster (Kim-Cohen and Turkewitz, 2012).

Interventions

Mass trauma events call for humanitarian assistance on different levels. The survivors of disasters and wars often present with the most urgent needs such as food, clean water,

and medical assistance. On the background of such salient shortages, mental health care is usually not perceived as a priority. However, different researchers have pointed to the importance of preventing and curing long-term mental health impairment that may interfere with functioning of individuals and communities. A particular challenge is that mass trauma mainly affects low- and middle-income countries with insufficient mental health service and limited availability of specialized professionals. Nevertheless, some first attempts have been made to develop and test prevention and intervention programs and principles, and some of these programs have shown promising effects in evaluation research (see below).

Mass trauma mental health programs vary with regard to their level of specialization (from universal to highly specialized services), the targeted ecological context (individual, family, school, community), and the timing in relation to the occurring mass trauma (immediate, intermediate, or long term). Universal interventions usually focus on more distal levels like schools and communities, and are often implemented early after incidents of mass trauma with the goal of preventing chronic pathological reactions. On the other hand, more specialized therapeutic interventions are located at more proximal levels, i.e., at the individual and family level. They target specific disorders rather than general distress and deal with identified cases that present with mental health disorders.

Different expert groups (e.g., Hobfoll et al., 2007) have formulated general and universal principles for the evidence-informed mental health response to mass trauma. The authors emphasize the promotion of conditions that are associated with recovery from trauma such as a sense of safety, calming, a sense of self and community efficacy, connectedness, and hope (Hobfoll et al., 2007). The idea is to create an environment that increases resilience and reduces risk factors across specific and unspecific interventions.

School-Based Programs

More specific preventive programs have been developed to support a healthy development of children affected by mass trauma. Most of these programs are school-based and aim at strengthening resilience and reducing symptoms of trauma-related distress in children with and without PTSD. School-based interventions are usually composed of modules such as psychoeducation, sociodrama, movement/dance, playful group cohesion activities, cognitive-behavioral stress inoculation techniques, as well as, in some programs, limited trauma exposure. Prominent examples of such programs are Classroom-Based Intervention (Macy et al., 2003), ERASE-Stress (Gelkopf and Berger, 2009), Overshadowing the Threat of Terrorism (Berger et al., 2007), and Teaching Recovery Techniques (Smith et al., 1999). Systematic evaluations of classroom-based programs in the context of mass trauma have been carried out in schools of Nepal, Indonesia, Sri Lanka, Palestine, and Uganda (Ager et al., 2011; Layne et al., 2008; Tol et al., 2008). The effects on psychological symptoms have often been moderate, but stronger effects have been found on resilience or protective factors, like prosocial behavior and hope (Barry et al., 2013). However, caution is warranted in the widespread implementation of classroom-based interventions in the context of mass disasters, as at least one study has shown that they might actually be harmful for some children as they interfere with natural recovery of the most severely affected children (Tol et al., 2012). An innovative new approach is the attempt to psychologically inoculate children against trauma reactions even before a mass trauma event occurs. Such a procedure is feasible in a conflict context with foreseeable escalation that will bring about threat in near future such as attacks on villages in Israel. Wolmer and colleagues (Wolmer et al., 2011) implemented a variant of stress inoculation training that teaches children techniques to cope with feelings of fear in a threatening situation. The authors show that this program might indeed prevent the onset of PTSD and stress reactions among children effectively when an attack occurs.

Group Psychotherapy

In contrast to classroom-based programs, other authors have adapted established forms of group psychotherapy to the context of mass trauma, in particular for severely affected children and adolescents living in war regions. This attempt requires the identification of single children with symptoms of PTSD or depression before treatment. For example, Bolton et al. (2007) investigated a group variant of interpersonal therapy (IPT) for depression in Northern Ugandan youths. IPT targets four interpersonal areas: (1) grief, (2) interpersonal disputes, (3) role transitions, and (4) interpersonal deficits. However, the effects of group IPT were limited to the reduction of depression symptoms among girls. Recently, McMullen and coworker (McMullen et al., 2013) evaluated a mixed individual and group-based variant of Trauma-Focused Cognitive-Behavioral Therapy (TF-CBT) for former male child soldiers and war-affected boys in the Democratic Republic of Congo (DRC). It was implemented by expert clinicians and included, next to various unspecific methods for stress management and relaxation, specific trauma-focused procedures such as creating a trauma narrative and cognitive processing. The authors showed a significant reduction of PTSD symptoms and comorbid distress. The same group (O'Callaghan et al., 2013) replicated this study with sexually exploited and war-affected girls in the DRC with local social workers as therapists and found promising effects. As a group treatment option for adults, Bass et al. (2013) have adapted and evaluated Cognitive Processing Therapy (CPT) for adult women who were sexually violated in the context of the civil war in the DRC (Bass et al., 2013). CPT aims to modify false beliefs and shattered assumptions related to the traumatic experience in group discussions. CPT effectively reduced anxiety and depression symptoms. Trained local assistants carried out the treatment.

Individual-Level Treatment

Outside the context of mass disasters, different variants of trauma-focused individual psychotherapy have been identified as the first-choice treatments of trauma-related disorders. All these approaches include a confrontation with the trauma memory in the form of the discussion of the meaning of the event or imaginative exposure to the memory, often

through a narrative reconstruction of the traumatic event. Trauma-focused therapies have been adapted to the context of mass trauma and evaluated. Grief and Trauma Intervention (Salloum and Overstreet, 2008) is one such approach for children that includes training in coping skills as well as the creation of a coherent trauma narrative through telling the story of the traumatic events. It has been applied in individual as well as in a group format, including a single individual session for exposure to the worst event. In a dismantling study of the effective ingredients of this treatment with disaster victims, a variant that did not include the trauma narration showed smaller effect sizes than the original treatment, which confirms the importance of the confrontation component of trauma treatment for children affected by mass disasters (Salloum and Overstreet, 2012). A well-established variant of trauma-focused therapy that had been specifically developed for victims of war and torture is Narrative Exposure Therapy (NET; Schauer et al., 2011). This treatment focuses exclusively on the processing of the trauma memory through documenting the life story of the survivors in detail. While NET has been originally developed for adults, it has been adapted to children as KIDNET. Both, the child and the adult version of this short treatment (4–12 sessions) have been tested in different populations (Robjant and Fazel, 2010) including refugees and war-affected populations. As individual treatment, NET might be more costly than a group- or classroom-based approach. However, the efficacy of this treatment, the superiority in comparison to different control conditions, and the feasibility in different contexts including unsafe regions have been well documented.

While current findings on developmental mass trauma reactions indicate the importance of family coping, the study of mass trauma programs that target the family level is still in its infancy. Testing the effects of a brief psychoeducation intervention offered to groups of parents living in a postconflict setting, Jordans and colleagues (Jordans et al., 2013) found beneficial effects on conduct problems among boys. Dybdahl et al. (2001) have found small positive effects of a mother empowerment program on mothers' mental health and the children's psychological functioning.

Taking together the evidence of mass trauma intervention and prevention, the findings argue for a stepped-care approach to prevent and alleviate psychological symptoms in children, adolescents, and adults. The key for any such approach is a systematic screening and triage to assign the affected children and adults to interventions that meet their demands. While the majority of survivors of mass traumas present with low to moderate levels of symptoms and distress and do not require any intervention, children presenting with moderate distress and low-level psychopathology should be assigned to school-based approaches that aim to strengthen their resources and coping skills. However, specialized clinical trauma-focused interventions (e.g., TF-CBT, NET) are required for those who fulfill criteria for mental health disorders, in particular PTSD. At the same time, North and Pfefferbaum (2013) have emphasized that disasters can also foster the reoccurrence and worsening of preexisting psychopathology, which will require a broad and functional mental health-care system next to special trauma interventions. The evidence clearly shows that, even for specialized trauma-focused psychotherapy, the employment of trained lay counselors or lay therapists within a care system that allows supervision and referral is an effective alternative in the absence of clinical professionals.

Abstract

Over the last four decades, few programs have been implemented as broadly or evaluated as thoroughly as those associated with mastery learning. This article describes how mastery learning originated and the essential elements involved in its implementation. It discusses the improvements in student learning that typically result from the use of mastery learning and how this strategy provides practical solutions to a variety of persistent instructional problems. Finally it explains the common misinterpretations of mastery learning and summarizes the results of research on its effects.

Over the last four decades, few programs have been implemented as broadly or evaluated as thoroughly as those associated with mastery learning. Programs based on mastery learning principles operate today in nations throughout the world and at every level of education. When compared to traditionally taught classes, students in mastery learning classes consistently have been shown to learn better, reach higher levels of achievement, and develop greater confidence in their ability to learn and in themselves as learners (Anderson, 1994; Guskey and Pigott, 1988; Klecker and Chapman, 2008; Kulik et al., 1990a; Miles, 2010).

This article describes how mastery learning originated and the essential elements involved in its implementation. It discusses the improvements in student learning that typically result from the use of mastery learning and how this strategy provides practical solutions to a variety of persistent instructional problems. Finally it explains the common misinterpretations of mastery learning and summarizes the results of research on its effects.

John B. Carroll's 'Model for School Learning'

Although the basic tenets of mastery learning can be traced to such early educators as Comenius, Pestalozzi, and Herbart, modern versions were inspired by a 1963 article by John B. Carroll of Harvard University entitled, 'A Model for School Learning.' In his article, Carroll challenged long-held perceptions of student *aptitude*. He pointed out that student aptitude traditionally had been viewed as the *level* to which a child could learn a particular subject. Children with high aptitude would be able to learn the most complex aspects of that subject, while those with low aptitude would be able to learn only the most basic elements. When aptitude is viewed in this way, children are seen as either good learners (high aptitude) or poor learners (low aptitude) with regard to the subject.

Carroll argued, however, that student aptitude more accurately reflects an indicator of *learning rate*. That is, all children have the potential to learn quite well, but differ primarily in terms of the time they require to do so. Some children are able to learn a subject very quickly while others may take much longer. When aptitude is viewed as an indicator of learning rate, children are seen not simply as good and poor learners, but rather as fast and slow learners.

Carroll then proposed a model for school learning based on this alternative view of aptitude. He believed that if each child was allowed the time needed to learn a subject to some criterion level, and if the child spent that time appropriately, then the child probably would attain the specified level of achievement. But if not enough time were allowed or if the child did not spend the time required, then the child would learn much less. The degree of learning attained by a child, therefore, could be expressed by the following simple equation:

$$\text{Degree of learning} = f\left(\frac{\text{time spent}}{\text{time needed}}\right)$$

In other words, degree of learning is a function of the time a child actually spends on learning, relative to the time he or she needs to spend. If the time spent was equal to time needed, the learning would be complete and the equation would equal 1. If the time spent was less than the time needed, however, the learning would be incomplete by that proportion.

Carroll further identified the factors that, he believed, influenced the time spent and the time needed. He argued that both of these elements were affected by characteristics of the learner and by characteristics of the instruction. Specifically, he believed that the time spent was determined by a child's *perseverance* and the *opportunity to learn*. Perseverance is simply the amount of time a child is willing to spend actively engaged in learning. Opportunity to learn is the classroom time allotted to the learning. In other words, time spent is determined by the child's persistence at a learning task and the amount of learning time provided. Time needed, on the other hand, Carroll believed was determined by the child's *learning rate* for that subject, the *quality of the instruction*, and the child's *ability to understand the instruction*. Specifically:

$$\text{Degree of learning} = f\left(\frac{\begin{array}{l} * \text{ perseverance} \\ * \text{ opportunity to learn} \end{array}}{\begin{array}{l} * \text{ learning rate} \\ * \text{ quality of instruction} \\ * \text{ ability to understand the instruction} \end{array}}\right)$$

Again, a child's learning rate is a measure of the time required by the child to learn the concepts or skills under ideal instructional conditions. If the quality of the instruction was high, then the child would readily understand it and would

probably need little time to learn. If the quality of the instruction was not as high, however, then the child would have greater difficulty understanding and would require much more time to learn. In other words, the quality of the instruction and the child's ability to understand the instruction interact to determine how much time is needed for the child to learn the concepts or skills.

Carroll's article made a significant contribution to learning theory. It set forth new guidelines for research into the concept of aptitude and identified specific factors that influence learning in school settings. His ideas about learning rate also prompted the development of numerous 'individualized instruction' programs that allowed students to progress through a series of learning units at their own, self-determined pace. Two of the best known of these 'continuous progress' programs were Individually Prescribed Instruction, developed at the University of Pittsburgh (Glaser, 1966) and Individually Guided Education, developed at the University of Wisconsin (Klausmeier et al., 1968). Carroll himself, however, did not address the problem of how to provide sufficient time or how to improve instructional quality. These issues were left unresolved.

Benjamin S. Bloom's 'Learning for Mastery'

Benjamin S. Bloom, Distinguished Service Professor at the University of Chicago, was impressed by the optimism of Carroll's perspective on learners and particularly by the idea that students differ in terms of the *time required* for learning rather than their *ability to learn*. If aptitude was indeed predictive of the time a child would require to learn, Bloom believed it should be possible to set the degree of learning expected of each child at some mastery performance level. Then by attending to the instructional variables under teachers' control – the opportunity to learn and the quality of the instruction – teachers should be able to ensure that every child attain that specified level.

To determine how this might be practically achieved, Bloom first considered how teaching and learning take place in typical group-based classroom settings. He observed that most teachers begin by dividing the concepts and skills that they want students to learn into smaller learning units. These units are usually sequentially ordered and often correspond to the chapters in the textbook used in teaching. Teachers then teach the unit concepts to all students in the same way, provide all students with the same amount of time to learn, and evaluate students' learning at the end with some form of test or assessment. The few students for whom the instructional methods and time were ideal learn excellently and perform well on the unit assessment. The largest number of students for whom the methods and time were only moderately appropriate learns less well. And students for whom the instruction and time were inappropriate due to differences in their backgrounds or learning styles, learn very little and perform poorly on the unit assessment. In other words, little variation in the teaching resulted in great variation in student learning. Under these conditions the pattern of student achievement was similar to the normal curve distribution shown in Figure 1.

Figure 1 Distribution of achievement in traditional classrooms.

To attain better results and *reduce* this variation in student achievement, Bloom reasoned that we would have to *increase* variation in the teaching. In other words, because students varied in their learning styles and aptitudes, teachers must diversify and differentiate instruction to better meet students' individual learning needs. The challenge was to find practical ways to do this within the context of group-based classrooms so that *all* students learn well.

In searching for such a strategy, Bloom drew primarily from two sources of evidence. First, he considered the ideal teaching and learning situation in which an excellent tutor is paired with each student. He was particularly influenced by the work of early pioneers in individualized instruction, especially Washburne (1922) and his Winnetka Plan, and Morrison (1926) and his University of Chicago Laboratory School experiments. In examining this evidence, Bloom sought to determine what crucial elements in one-to-one tutoring and individualized instruction could be transferred to group-based classroom settings.

Second, Bloom looked at studies of the learning strategies of academically successful students, especially the work of Dollard and Miller (1950). From this research he tried to identify the activities of high-achieving students in group-based classrooms that distinguish them from their less successful classmates.

Bloom saw value in teachers' traditional practice of organizing the concepts and skills they want students to learn into learning units. He also considered it important for teachers to assess student learning at the end of each unit. But the classroom assessments most teachers used seemed to do little more than show for whom their initial instruction was and was not appropriate.

Bloom believed that a far better approach would be for teachers to use their classroom assessments as learning tools, and then to follow those assessments with a *feedback and corrective* procedure. In other words, instead of using assessments only as evaluation devices that mark the end of each unit, Bloom recommended using them as part of the instructional process to *diagnose* individual learning difficulties (feedback) and to *prescribe* remediation procedures (correctives).

This is precisely what takes place when an excellent tutor works with an individual student. If the student makes an error, the tutor first points out the error (feedback) and then follows up with further explanation and clarification (correctives) to ensure the student's understanding. Similarly, academically successful students typically follow up the mistakes they make on quizzes and assessments. They ask the teacher about the items they missed, look up the answer in the textbook or other

resources, or rework the problem or task so that they do not repeat those errors.

With this in mind, Bloom outlined an instructional strategy to make use of this feedback and corrective procedure, labeling it 'learning for mastery' (Bloom, 1968), and later shortening it to simply 'mastery learning' (Bloom, 1971a). With this strategy, teachers first organize the concepts and skills they want students to learn into learning units that typically involve about a week or two of instructional time. Following initial instruction on the unit, teachers administer a brief quiz or assessment based on the unit's learning goals. Instead of signifying the end of the unit, however, this assessment's purpose is to give students information, or 'feedback,' on their learning. To emphasize this new purpose Bloom suggested calling it a *formative assessment*, meaning 'to inform or provide information.' A formative assessment identifies for students precisely what they have learned well to that point, and what they need to learn better (Bloom et al., 1971).

Paired with each formative assessment are specific 'corrective' activities for students to use in correcting their learning difficulties. Most teachers match these 'correctives' to each item or set of prompts within the assessment so that students need work on only those concepts or skills not yet mastered. In other words, the correctives are 'individualized.' They may point out additional sources of information on a particular concept, such as page numbers in the textbook or workbook where the concept is discussed. They may identify alternative learning resources such as different textbooks, learning activities, alternative materials, CDs, digital lessons, or web-based instructional materials (DeWeese and Randolph, 2011). Or they may simply suggest sources of additional practice, such as study guides, computer exercises, independent or guided practice activities, or collaborative group activities.

With the feedback and corrective information gained from the formative assessment, each student has a detailed prescription of what more needs to be done to master the concepts or skills from the unit. This 'just-in-time' correction prevents minor learning difficulties from accumulating and becoming major learning problems. It also gives teachers a practical means to vary and differentiate their instruction in order to better meet students' individual learning needs. As a result, many more students learn well, master the important learning goals in each unit, and gain the necessary prerequisites for success in subsequent units.

When students complete their corrective activities after a class period or two, Bloom recommended they take a *second* formative assessment. This second, 'parallel' assessment covers the same concepts and skills as the first, but is composed of slightly different problems or questions, and serves two important purposes. First, it verifies whether or not the correctives were successful in helping students overcome their individual learning difficulties. Second, it offers students a second chance at success and, hence, has powerful motivational value (Changeiywo et al., 2011).

Some students, of course, will perform well on the first assessment, demonstrating that they have mastered the unit concepts and skills. The teacher's initial instruction was highly appropriate for these students and they have no need of corrective work. To ensure their continued learning progress, Bloom recommended that teachers provide these students with special 'enrichment' or 'extension' activities to broaden their learning experiences. Enrichment activities are often self-selected by students and might involve special projects or reports; digital academic games; or any variety of complex, problem-solving tasks. Figure 2 illustrates this instructional sequence.

Figure 2 The mastery learning instructional process.

Through this process of formative classroom assessment, combined with the systematic correction of individual learning difficulties, Bloom believed all students could be provided with a more appropriate quality of instruction than is possible under more traditional approaches to teaching. As a result, nearly all might be expected to learn well and truly master the unit concepts or learning goals (Bloom, 1976). This, in turn, would drastically reduce the variation in students' achievement levels, eliminate achievement gaps, and yield a distribution of achievement more like that shown in Figure 3.

In describing mastery learning, however, Bloom emphasized that reducing variation in students' achievement does not imply making all students the same. Even under these more favorable learning conditions, some students undoubtedly will learn more than others, especially those involved in enrichment activities. But by recognizing relevant, individual differences among students and then altering instruction to better meet their diverse learning needs, Bloom believed the variation among students in how well they learn specific concepts or master a set of articulated learning goals could eventually reach a 'vanishing point' (Bloom, 1971b). In other words, *all* students would be helped to learn well the knowledge and skills prescribed in the curriculum. As a result, gaps in the achievement of different groups of students would be closed (Guskey, 2007).

Figure 3 Distribution of achievement in mastery learning classrooms.

The Essential Elements of Mastery Learning

After Benjamin Bloom described his ideas, several of his students took up the task of clarifying mastery learning instructional strategies (e.g., Block et al., 1989) and numerous programs based on mastery learning principles sprung up in schools throughout the United States and around the world (see Postlethwaite and Haggarty, 1998; Reezigt and Weide, 1990; Wu, 1994; Yildiran, 2006; Yildiran and Aydin, 2005). Although differing from setting to setting, those programs true to Bloom's ideas include two essential elements: (1) the *feedback, corrective, and enrichment process*; and (2) *instructional alignment* (Guskey, 1997a).

Feedback, Correctives, and Enrichment

Teachers who use mastery learning provide students with frequent and specific *feedback* on their learning progress through regular, formative classroom assessments. This feedback is both diagnostic and prescriptive. It reinforces precisely what students were expected to learn, identifies what they learned well, and describes what needs to be learned better. The US National Council of Teachers of Mathematics (NCTM) emphasizes this same element in its latest iteration of the standards for school mathematics. To overcome inequities in mathematics instruction, NCTM stresses the use of assessments that support learning and provide useful information to both teachers and students (NCTM, 2000).

Feedback alone, however, does little to help students improve their learning. Significant improvement requires that feedback be paired with *correctives*: activities that offer guidance and direction to students on how to remedy their learning problems. Because of students' individual differences, no single method of instruction works best for all. To help every student learn well, therefore, teachers must differentiate their instruction, both in their initial teaching and especially through the corrective activities (Bloom, 1976). In other words, teachers must *increase* variation in their teaching to *decrease* variation in results.

To be effective, correctives must be qualitatively different from the initial teaching. They must provide students who need it with an alternative approach and additional time to learn. The best correctives present concepts differently and involve students in learning differently than did the initial instruction. They incorporate different learning styles, learning modalities, or types of intelligence. Although developing effective correctives can prove challenging, many schools find that providing teachers with time to work collaboratively, sharing ideas, materials, and expertise, greatly facilitate the process (Guskey, 2008).

Most applications of mastery learning also include *enrichment* or *extension* activities for students who master the unit concepts from the initial teaching. As described above, enrichment activities offer students exciting opportunities to broaden and expand their learning. They reward students for their learning success and challenge them to go further. Many teachers draw from activities developed for gifted and talented students when planning enrichment activities, both to simplify implementation tasks and to guarantee these students a high-quality learning experience.

Teachers implement the feedback, corrective, and enrichment process in a variety of ways. Many use short, paper-and-pencil quizzes as formative assessments to give students feedback on their learning progress. But formative assessments also can take the form of essays, compositions, projects, reports, performance tasks, skill demonstrations, oral presentations, or any device used to gain evidence on students' learning progress. In essence, teachers adapt the format of their formative assessments to match their instructional goals.

Following a formative assessment, some teachers divide the class into separate corrective and enrichment groups. While the teacher directs corrective activities, guaranteeing that all students who need the extra time and assistance take part, the other students work on self-selected, independent enrichment activities. Other teachers pair with colleagues and use a team-teaching approach. While one teacher oversees corrective activities, the other monitors enrichments. Still other teachers use cooperative learning activities in which students work together in teams to ensure all reach the mastery level. Since students have their own personal scores on the formative assessment, individual accountability is assured. Offering the entire team special recognition or credit if all members attain mastery on the second formative assessment encourages group responsibility.

Feedback, corrective, and enrichment procedures are crucial to mastery learning, for it is through these procedures that mastery learning differentiates and individualizes instruction. In every learning unit, students who need extended time and opportunity to remedy learning problems receive these through the correctives. Students who learn quickly and find the initial instruction highly appropriate have opportunities to extend their learning through enrichment. As a result, all students experience more favorable learning conditions and more appropriate, higher-quality instruction (Bloom, 1977; Guskey, 2010).

Instructional Alignment

While feedback, correctives, and enrichment are important, they alone do not constitute mastery learning. To be truly effective, Bloom stressed they must be combined with the second essential element of mastery learning: *instructional alignment*. Reducing variation in student learning and closing achievement gaps require clarity and consistency among all instructional components (Bloom, 1971a).

Bloom believed three major components compose the teaching and learning process. To begin there must be specific ideas about what students are expected to learn and be able to do, that is, *learning goals or standards*. Next comes *instruction* that, ideally, results in *proficient learners* – students who have learned well and whose proficiency can be assessed through some form of assessment or evaluation. Mastery learning adds a feedback and corrective component, allowing teachers to determine for whom their initial instruction was appropriate and for whom an alternative approach may be needed.

Although essentially neutral with regard to what is taught, how it is taught, and how learning is assessed or evaluated, mastery learning requires consistency or alignment among these instructional components, as shown in **Figure 4**. For example, if students are expected to learn higher-level skills such as those involved in making applications, solving complex problems, or developing thoughtful analyses, mastery learning stipulates that instructional activities must be planned

Figure 4 Major components in the teaching and learning process.

to give students opportunities to practice and actively engage in those skills. It also requires that students be given specific feedback on how well they have learned those skills, coupled with directions on how to correct any learning errors. Finally, procedures for assessing or evaluating students' learning should reflect those higher-level skills as well.

To ensure alignment among instructional components, teachers must make a number of crucial decisions. First, they need to decide what concepts or skills are most important for students to learn and most central to students' understanding. Teachers must determine, for example, if they want students to learn only basic skills, or if they want students to develop higher-level skills and more complex cognitive processes. Second, teachers need to decide what evidence best reflects students' mastery of those basic or higher-level skills. Critics sometimes challenge teachers' abilities to make these crucial decisions. But, in essence, teachers at all levels already make these decisions in conducting regular classroom activities. Every time they administer an assessment, grade a paper, or evaluate students' learning, teachers communicate to students what is most important to learn. Using mastery learning simply compels teachers to make these decisions more thoughtfully, intentionally, and purposefully.

Misinterpretations of Mastery Learning

Shortly after Bloom presented his ideas on mastery learning, misinterpretations began to occur. Some early attempts to apply mastery learning, for example, were based on narrow and inaccurate understandings of Bloom's theory. These efforts focused only on low-level cognitive skills, attempted to break learning down into small segments, and insisted that students 'master' each segment before being permitted to move on. Teachers were regarded in these programs as little more than managers of materials and record-keepers of student progress. Unfortunately, similar misinterpretations of mastery learning continue today.

Nowhere in Bloom's writing, however, can this kind of narrowness and rigidity be found. In fact, Bloom emphasized quite the opposite. He considered thoughtful and reflective teachers vital to the successful implementation of mastery learning and continually stressed flexibility in its application. In his earliest description of the process Bloom wrote:

> There are many alternative strategies for mastery learning. Each strategy must find some way of dealing with individual differences in learners through some means of relating the instruction to the needs and characteristics of the learners. … The nongraded school is one attempt to provide an organizational structure that permits and encourages mastery learning.
>
> Bloom, 1968, pp. 7–8

Bloom further emphasized his belief that instruction in mastery learning classrooms should focus on higher-level learning goals, not simply basic skills. He noted:

> I find great emphasis on problem solving, applications of principles, analytical skills, and creativity. Such higher mental processes are emphasized because this type of learning enables the individual to relate his or her learning to the many problems he or she encounters in day-to-day living. These abilities are stressed because they are retained and utilized long after the individual has forgotten the detailed specifics of the subject matter taught in the schools. These abilities are regarded as one set of essential characteristics needed to continue learning and to cope with a rapidly changing world.
>
> Bloom, 1978, p. 578

Modern research studies have shown mastery learning to be particularly effective when applied to instruction focusing on higher-level learning goals such as problem solving, drawing inferences, deductive reasoning, and creative expression (Arredondo and Block, 1990; Kozlovsky, 1990; Mevarech, 1981; Zimmerman and Dibenedetto, 2008). When well implemented, the process helps teachers improve student learning and close achievement gaps in a broad range of learning goals from basic skills to highly complex cognitive processes.

Another misinterpretation comes from educators who believe that the constraint of limited class time will inhibit efforts to implement mastery learning (Guskey, 1997a). They assume that the introduction of feedback, corrective, and enrichment procedures will reduce the amount of material teachers will be able to cover. In other words, teachers will have to sacrifice *coverage* for the sake of *mastery*. But as discussed earlier, minor alterations in instructional pacing typically resolve this concern.

Early mastery learning units usually do require more time. Teachers who allow class time for students to complete corrective activities often find themselves 'behind' other teachers who teach in more traditional ways after the first two or three units. But once students become familiar with the process, mastery learning teachers generally pick up their pace. Since students in mastery learning classes spend a larger portion of their time actively engaged in learning, they make more rapid progress than students in more traditionally taught classes (Fitzpatrick, 1985). As students catch on to the process, they also do better on first formative assessments. With fewer students involved in correctives and less corrective work needed, teachers reduce the class time allocated to corrective activities. And because mastery learning students learn well the concepts and skills from early units, they are better prepared for later, more advanced units. Instruction in later units can therefore be more rapid and include fewer review activities. Most teachers discover that with slight adjustments in the pacing of their instruction – slightly more time spent in early units but less time in later ones – they can cover just as much material using mastery learning, and in

some cases more, as they were able to using more traditional approaches to instruction (Block, 1983).

Research Results and Implications

Teachers who implement mastery learning generally find that it requires only modest changes in their instructional procedures. Excellent teachers use many aspects of mastery learning in their classes already, and others discover that the process blends well with their current teaching strategies. This makes mastery learning particularly attractive to teachers at all levels, especially considering the difficulties associated with new approaches that require major changes in teaching procedures.

Despite the modest nature of these changes, however, extensive research evidence shows that the use of mastery learning can have exceptionally positive effects on student learning (Block et al., 1989; Guskey and Pigott, 1988; Miles, 2010). Evidence gathered in Africa (Changeiywo et al., 2011), Asia (Wu, 1994; Yildiran and Aydin, 2005), Australia (Chan, 1981), Europe (Langeheine, 1992; Mevarech, 1985; Reezigt and Weide, 1990), South America (Cabezon, 1984), and the United States (Walberg, 1990) shows the careful and systematic application of these elements can lead to significant improvements in student learning outcomes. Some researchers even suggest that the superiority of Japanese students in international comparisons of achievement in mathematics operations and problem solving may be due largely to the widespread use in Japan of instructional practices similar to mastery learning (Nakajima, 2012; Waddington, 1995).

Long-term investigations have yielded similarly impressive results. A study by Whiting et al. (1995), for example, representing 18 years of data gathered from over 7000 high school students showed mastery learning to have remarkably positive influence on students' test scores and grade-point averages as well as their attitudes toward school and learning. Another field experiment conducted in elementary and middle school classrooms showed that the implementation of mastery learning led to significantly positive increases in students' academic achievement and their self-confidence (Anderson et al., 1992). Even more impressive, a comprehensive, meta-analysis review of the research on mastery learning by Kulik et al. (1990a) concluded:

> We recently reviewed meta-analyses in nearly 40 different areas of educational research (J. Kulik and Kulik, 1989). Few educational treatments of any sort were consistently associated with achievement effects as large as those produced by mastery learning. … In evaluation after evaluation, mastery programs have produced impressive gains.
>
> Kulik et al., 1990a, p. 292

Similarly, in *Research on Educational Innovations*, Ellis and Fouts (1993) conclude: "the research on mastery learning is about as strong as one can find in the annals of educational investigation. Study after study indicates the superiority of mastery learning over traditional methods of instruction" (p. 112).

Research evidence also shows that the positive effects of mastery learning are not limited to cognitive or achievement outcomes. The process also yields improvements in students' confidence in learning situations, school attendance rates, involvement in class sessions, attitudes toward learning, and a variety of other affective measures (Block et al., 1989; Changeiywo et al., 2011; Guskey and Pigott, 1988; Whiting and Render, 1987). This multidimensional impact has been referred to as the 'multiplier effect' of mastery learning and makes it one of the most cost-effective means of educational improvement.

It should be noted that one review of the research on mastery learning, contrary to all other reviews, indicated that the process had essentially no effect on student achievement (Slavin, 1987). This finding surprised not only scholars familiar with the vast research literature on mastery learning showing it to yield very positive results, but also large numbers of practitioners who had experienced its positive impact first hand. A close inspection of this review shows, however, that it was conducted using techniques of questionable validity (Hiebert, 1987), employed capricious selection criteria (Kulik et al., 1990b), reported results in a biased manner (Bloom, 1987; Walberg, 1988), and drew conclusions not substantiated by the evidence presented (Guskey, 1987, 1988). Most importantly, three much more extensive and methodologically sound reviews published since (Guskey and Pigott, 1988; Kulik et al., 1990a; Miles, 2010) have verified mastery learning's consistently positive impact on a broad range of student learning outcomes and, in one case (i.e., Kulik et al., 1990b), showed clearly the distorted nature of this earlier report.

Conclusion

Researchers today generally recognize the value of the essential elements of mastery learning and their importance in effective teaching at any level of education. As a result, fewer studies are being conducted on the mastery learning process, per se. Instead, researchers are looking for ways to enhance results further, adding additional elements to the mastery learning process that positively contribute to student learning in hopes of attaining even more impressive gains (Bloom, 1984). Recent work on the integration of mastery learning with other innovative strategies appears especially promising (Guskey, 1997b; Guskey and Jung, 2011).

In his later writing Bloom, too, described exciting work on other ideas designed to attain results even more positive than those typically achieved with mastery learning (Bloom, 1984). These ideas stemmed from the work of two of Bloom's doctoral students, Anania (1981) and Burke (1983), who compared student learning under three different instructional conditions. The first was *conventional instruction* in which students were taught in group-based classes that included about 30 students and where periodic assessments were given mainly for the purposes of grading. The second was *mastery learning*, where students again were taught in group-based classes of about 30 students but were administered regular 'formative' assessments for feedback, followed by individualized corrective instruction and parallel second assessments to determine the extent to which they mastered specific learning goals. The third was *tutoring*, where a good tutor was paired with each student. Under tutoring students were also administered regular formative assessments, along with

corrective procedures and parallel second assessments, although the need for corrective work under tutoring was usually quite small.

The differences in students' final achievement under these three conditions were striking. Using the standard deviation (sigma) of the control (conventional) class as the measure of difference, Bloom's students discovered that:

> The average student under tutoring was about two standard deviations above the average of the control class (the average tutored students was above 98% of the students in the control class). The average student under mastery learning was about one standard deviation above the average of the control class (the average mastery learning student was above 84% of the students in the control class). … Thus under the best learning conditions we can devise (tutoring), the average student is 2 sigma above the average control student taught under conventional group methods of instruction.
>
> Bloom, 1984, p. 4

Bloom referred to this as the '2 Sigma Problem':

> The tutoring process demonstrates that *most* students do have the potential to reach this high level of learning. I believe an important task of research and instruction is to seek ways of accomplishing this under more practical and realistic conditions than the one-to-one tutoring, which is too costly for most societies to bear on a large scale. This is the '2 Sigma' problem. Can researchers and teachers devise teaching-learning conditions that will enable the majority of students under *group instruction* to attain levels of achievement that can at present be reached only under tutoring conditions?
>
> Bloom, 1984, pp. 4–5)

Bloom believed that attaining this high level of achievement would probably require more than just improvements in the quality of group instruction. Researchers and teachers might also need to find ways of improving students' learning processes, the curriculum and instructional materials, the home environmental support of students' school learning, and providing a focus on higher-level thinking skills. Nevertheless, Bloom remained convinced that careful attention to the elements of mastery learning would allow educators at all levels to make great strides in their efforts to reduce the variation in student achievement, close achievement gaps, and help all children to learn excellently.

Abstract

All societies depend on natural resources to feed, house, and transport people and to produce the goods and services everyday life depends upon. The magnitude of the physical interaction between society and nature may be measured through material flow accounting. The accounts measure the amount of materials extracted domestically – biomass, fossil fuels, metal ores, and construction materials – as well as traded materials and also measure the disposal of waste and emissions to the environment by taking a whole life cycle perspective. The accounts measure yearly material flows in tonnes and provide an information base about the scale of natural resource use that underpins human development and economic prosperity. Material flow accounts have become part of the system of integrated economy–environmental accounts and inform modern environmental policy making that understands environmental outcomes are greatly related to the process of consumption and production. Indicators based on material flow accounts play a major role in the environmental policy process and figure prominently in international debates about sustainable consumption and production, resource efficiency and decoupling, and the green economy.

Introduction

The study of material flow accounting (MFA) focuses on the natural resource requirements of national economies, specific economic activities (such as construction and housing, transport, and mobility), or geographical units such as cities. MFA accounts for the input of primary materials – biomass, fossil fuels, metal ores, and minerals – and semimanufactures and final goods into economic activities. MFA also accounts for the outputs of economic systems including final goods for export, waste, and emissions. MFA often conceptualizes the economic system as a 'black box.' There are, however, accounting strategies for material flows within economic systems available as well.

Material flow accounts are complementary to economic accounts and measure tonnes of materials that are associated with production and consumption processes. The accounts measure the physical implications of economic systems and allow links to be established between economic activities and the natural resource base and natural environment they depend upon. Material flow accounts can therefore be used as tools in both environmental and economic policy. Material flow accounts have grown in political importance over the past decade in response to converging environmental and economic pressures such as climate change, food security, rising energy costs, and the global financial crisis of 2008.

MFA has a sound theoretical base in the theory of social-ecological systems and the concept of social metabolism and industrial metabolism (Ayres and Simonis, 1994). MFA operationalizes the concept of metabolism, provides an understanding of the amounts of natural resources used in different economies at different times in history, and has a multitude of application scales – global, regional, national, subnational, urban, businesses, and households – and a variety of policy applications in the context of integrated economic and environmental policy making.

History of MFA

For a long time, there has been recognition that all economic activities depend on the timely availability and affordability of natural resources. Major economic powers such as the Soviet Union and the United States of America have established accounts of their natural resource base and resource requirements and the supply systems that deliver those resources. The most prominent example is the Paley report of the 1950s (Paley, 1952) comparing the resource base of the United States and its allies to those of the Soviet Union.

Early research that pioneered a physical accounting approach in economics includes the work of Nicholas Georgescu-Roegen, Herman Daly, and Robert Ayres. Georgescu-Roegen was one of the first economists who assessed the interplay of economic activity and the natural environment within the concept of thermodynamics (Georgescu-Roegen, 1971). Herman Daly introduced the notion of scale referring to the total volume of resource flows: the matter–energy throughput taken from the environment as low-entropy resources and returned to the environment as high-entropy waste. Scale, according to Daly, is relative to environmental carrying capacity and is often ignored by mainstream economics (Daly, 1992). Robert Ayres published an early material flow account for the United States that set an analytical standard for the next generation of MFA studies (Kneese et al., 1970).

National material flow accounts were pioneered in Germany, Japan, and Austria in the early 1990s (Fischer-Kowalski and Hüttler, 1998). The World Resources Institute published two groundbreaking comparative studies "Resource Flows: The Material Basis of Industrial Economies" (Adriaanse et al., 1997) and "The Weight of Nations" (Matthews et al., 2000) that highlighted differences in methodology and triggered a process of methodological harmonization and standardization. The European statistical office – EUROSTAT – has since been fine-tuning methods and has produced several iterations of the

MFA methods guidebook (Eurostat, 2012). The OECD, supported by a political decision of the leadership of the group of eight (G8) at Sea Island in 2008, identified the policy implications of MFA data and indicators in a series of reports and further supported the process of standardization of material flow and resource productivity information (OECD, 2008). Most recently, MFA was integrated into the system of environmental–economic accounting helping to establish a sound base for environmental accounts at national, regional, and global levels (UN, 2014).

The sustainable development discourse that emerged in the 1990s profoundly changed the way in which the policy community viewed environmental problems. The new sustainability discourse helped establish the notion of decoupling of economic activities from environmental pressures and impacts. In essence, sustainable development suggested a new path to development in which the exploitation of natural resources, the direction of investments, the orientation of technological development, and institutional change are all in harmony and enhance the current and future potential of socioeconomic systems to meet human needs and aspirations.

As a consequence of the new sustainable development discourse, many national governments and international organizations such as the United Nations have moved from a conservationist approach in environmental politics to a new understanding of the social and economic drivers that cause environmental pressures. MFA measures a specific aspect of environmental pressures and allows progress in resource efficiency and decoupling to be assessed. This new policy orientation has inspired a large number of global and regional studies into natural resource use and economic development.

Scientifically, MFA is used as a data organization strategy and an analytical tool in the research fields of industrial ecology and ecological economics, but also figures prominently in physical environmental history (Krausmann et al., 2008) and environmental sociology (Fischer-Kowalski and Haberl, 1997).

Accounting Standards and Headline Indicators

MFA assembles data on material use, often at the national level. The accounting is based on the concept of industrial metabolism and starts from a clear definition of system boundaries between economy and nature (and national borders between economies) and an assessment of physical stocks, for example, buildings and transport infrastructure, but also livestock animals and people. It measures the yearly flows of materials required to fuel and maintain existing stocks, to replace stock that has become depreciated, and to build new stock. The accounts provide data on material inputs into, the changes in material stock within, and the material outputs in the form of goods for exports or discharge of waste and emissions to the domestic environment of an economy. MFA covers all solid, gaseous, and liquid materials that are mobilized in economic activities with the exception of bulk water and air. Water is usually treated in a separate water account and air is dealt with as a memorandum item when closing the material balance of an economy.

The unit of measurement of an MFA is most commonly (metric) tonnes. Inputs are distinguished by their origin, i.e., whether they are extracted domestically (domestic extraction, DE) or are imported goods from other countries (imports, IM and exports, EX). Primary material inputs are most commonly grouped into four main aggregate material groups: biomass (renewable), and fossil fuels, metal ores, and industrial and construction minerals (nonrenewable). The outputs are distinguished by gateways through which they leave the economy and include goods exported, waste to landfill, and emissions to air and water. Material flow accounts aim for close complementarity with economic accounts and include materials at the commodification stage, i.e., when a natural resource becomes a primary material and a market value is attached. In order to provide a complete picture of the physical interaction of the economy with the environment, this complementarity to economic accounts cannot always be upheld and the accounts include a number of inputs that have no market value attached. This is the case for biomass grazed and scavenged by livestock, crop residues that are used economically in the context of a farm, the waste rock component of metal ores, and sand and gravel that is extracted within the confines of a construction company on the premises of the company to mention the most important categories. Overall, material flows that have no market value attached make up 20% of global materials extraction.

Materials that are mobilized in the course of economic activities but do not enter the production process as such are classified as unused extraction. They may include earth movement in mining and agriculture, by-catch in fisheries, and by-harvest of timber and are usually left where they occur. These flows are classified as unused DE (**Figure 1**).

A full material flow dataset hence comprises all economically relevant material exchanges and enables the construction of a set of indicators. These are increasingly used by national governments and businesses. The standard headline indicators derived from an MFA account include the following:

Direct material input (DMI), which measures the overall material input into a national economy and is calculated as the sum of DE and imports (DMI = DE + IM).

The *physical trade balance (PTB)* is a measure of net trade and is calculated as the difference between imports and exports. The PTB is the reverse of the monetary terms of trade

Figure 1 The material cycle.

and shows whether a country is a net importer of materials and hence depending on the world market for primary materials to satisfy the physical requirements of its economy, or a net exporter supplying primary resources to global markets (PTB = IM – EX).

Domestic material consumption (DMC) is a measure of apparent consumption of an economy and is calculated by adding imports and subtracting exports from DE of materials (DMC = DE + IM – EX or DMC = DE + PTB).

Domestic processed output (DPO) provides a comprehensive measure of all materials that leave an economy at any stage. Included in DPO are emissions to air, industrial and household waste deposited in landfill, material loads in wastewater, and materials dispersed into the environment as a result of product use.

Net additions to stock (NAS) measures the yearly addition to the stock of buildings, transport infrastructure, productive capacity, and durable consumer goods. It subtracts materials that are discarded from gross additions to stock (NAS = DMI – DPO – EX).

MFA accounts are a first step toward a satellite account for materials to the system of national accounts (SNA) and provide a rich analytical database and indicators to inform modern, integrated economic and environmentally minded policy decisions.

The complementarity of MFA and national accounts allows material efficiency (ME) indicators to be calculated. The ME is usually expressed as material intensity, i.e., the amount of material required per unit of economic output. It is measured by dividing DMC by gross domestic product (GDP). Efficiency can also be expressed as material productivity (GDP/DMC) which is the inverse of material intensity.

Most studies and policy reports to date have focused on these indicators and hence have presented a production-focused perspective on the material requirements, waste and emissions of economies. In the context of global concern for resource supply security and global fairness a consumption-based approach to material use has been introduced, to complement other consumption-based indicator systems such as those for energy use (Wiedmann, 2009) and carbon emissions (Hertwich and Peters, 2009) which have pioneered consumption-based analysis. When countries import goods, the primary resources required to produce those goods remain in the country of origin. At the same time, when a country exports goods the primary resources required to produce the good remain in the country. Traded goods are measured at the time when they cross the boundary between countries (direct imports and exports) but they are related to an indirect material requirement referred to as the raw material equivalent (RME). RME refers to the primary materials that were required to produce the goods and can be measured with various analytical techniques (Munoz et al., 2009).

More recently, the notion of *material footprint (MF)* of consumption was introduced (Wiedmann et al., 2013). The MF of an economy is accounted for through the attribution of global material extraction to final consumption in a country and requires a global, multiregional input–output framework as an analytical tool. Alternatively, the upstream and downstream requirements of traded goods could also be measured by employing life cycle analysis coefficients REF. Both approaches have been tested but are still considered immature with regard to the robustness and reliability of results. Technically, MF can be expressed as DE plus the RME of imported goods, RME_{IM} minus the RME of exported goods, RME_{EX} ($MF = DE + RME_{IM} - RME_{EX}$).

The MF indicator allows the establishment of a revised ME indicator which is sensitive to the burden shifting that occurs between nations importing and exporting natural resources. Material intensity is now measured by dividing MF by GDP.

Applications of MFA

Most commonly, material flow accounts are established for national economies. These accounts complement economic accounts and report progress in the ME of nations. Such accounts now exist for most OECD countries and a number of developing countries. While early studies focused on descriptive aspects of a country's material use, the level of analytical sophistication has continued to increase. More recent studies discuss the social and economic drivers of material use, look at the economic structure of a country and the role the country plays in the world economy, analyze trade patterns and their material underpinnings, and unpack policy implications of material flow accounts.

Material flow accounts often conceptualize the economy as a black box and focus on those inputs and outputs for which data are more easily accessible than for material exchanges within an economy. As a consequence, material flow accounts for specific economic activities have been rare. To gain a good understanding of the material interrelationships within a national economy requires a full physical input–output table (PIOT) of that economy. Establishing such a table is very data and time intensive and for this reason PIOTs are often outdated when they are published. PIOTs do, however, exist for Denmark and Germany (Weisz and Duchin, 2006) and provide in-depth insight into the material interactions within those economies.

Material flow accounts for cities have been another focus of the research community and many case studies have become accessible recently. Urban material flow accounts also have a long history and go all the way back to the early work of Stephen Boyden (Boyden et al., 1981) and Abel Wolman (Wolman, 1965). Accounting for urban metabolism using similar accounting strategies to national MFA has become a very active area of research more recently (Weisz and Steinberger, 2010).

During the past two decades, material supply and demand relationships in the world economy have become ever more complex and have introduced a new focus in MFA, looking at upstream and downstream material requirements for traded goods.

Globalization of production and consumption processes has increased the spatial disconnect between primary natural resource supply and centers of demand and has added complexity to societies' metabolism. In many economies, a proportion of resources extracted domestically is used for the production of traded goods while at the same time high-end processed goods with substantial amounts of embodied materials and energy are imported. Standard MFA does not

distinguish whether resources are extracted to satisfy domestic or foreign final demand and the structure of production and the origin of material inputs remains unknown within the 'black box' that represents an economy. Environmentally extended input–output analysis (EE-IOA) based on the work of economist Wassily Leontief (Leontief, 1970) supports the analysis of production structure and intra-industry relationships within the 'black box.'

MFA and EE-IOA cover the flows of material, energy, and money within the economy, but not accumulated physical and monetary capital or the stocks of buildings, infrastructure, productive capital, and durable consumer goods which play a central role in the economy, and in consumption and everyday life. They provide physical services such as shelter, mobility, and industrial capacity, representing large accumulations of material and investment. They are usually long lived and their depreciation time determines the amount of material required to maintain or replace them. Physical stock also determines the speed at which new technologies can penetrate markets, and there are technical properties that link service provision with energy and material throughput. Understanding the dynamic properties of physical stock in use is the subject of dynamic stock modeling (Muller, 2006).

MFA has also underpinned a variety of local studies, mostly in developing countries REF looking into the current metabolic transition, and historical studies of social metabolism providing long-time accounts (centuries) of industrial development and changing natural resource bases (Fischer-Kowalski et al., 2011). MFA data and indicators have assisted in empirically exploring the nonlinear relationship between material and energy use and human development (Steinberger and Roberts, 2010).

Policy Use

The information provided by material flow accounts is increasingly being used by the policy and business communities. Most notably, material flow accounts have become an essential part of environmental satellite accounts to the SNA and offer an alternative to the green accounting approaches of the 1970s and 1980s (Bartelmus, 2003). Material flow data show the quantity of natural resources required per unit of output in a national economy, for a certain economic sector or activity, and provide insight into the eco-efficiency of the production process in different countries and different economic sectors. They allow for benchmarking and target setting and for monitoring progress in resource efficiency and waste minimization. They also form an important part of triple bottom line accounting in businesses and industries (Foran et al., 2005).

Material flow accounts allow the creation of a set of pressure indicators to monitor the physical flow of natural resources and waste and emissions between economy and environment. Pressure indicators allow for a swift policy response, even before pressures have led to changes in the state of the environment and are causing visible impacts. This allows much shorter response times for environmental policy making with regard to major environmental problems including the depletion of natural resources, climate change, biodiversity loss, and problems related to growing amounts of household and industrial waste.

Decoupling has become a signature concept of modern integrated economic–environmental policy (UNEP, 2011a) and refers to the ability to expand the economy while reducing material and energy use, as well as waste and emissions. This may occur through the adoption of new technologies and innovations in major systems of provision including agriculture and food, construction and housing, and transport and mobility but also in heavy industries such as iron and steel, cement, and paper production. Decoupling is based on the idea of achieving more human well-being with less environmental disruption. The potential for efficiency gains is very large in many sectors of the economy, sometimes up to 80% (Von Weizsaecker et al., 2009).

The new policy concepts of sustainable consumption and production, resource efficiency and waste minimization, and investing in a green and low carbon economy depend on information about material flows to set objectives and targets, monitor progress, and evaluate policy outcomes. Many countries and regional bodies have developed their national strategies and framework policies to deliver human development and economic growth while minimizing natural resource depletion and environmental degradation. Examples include the European Union Resource Strategy supporting a resource-efficient Europe (EU, 2011) and the material flow accounts delivered by member countries and published by the European statistical office to monitor progress, the Chinese law to promote a circular economy (UNEP, 2011b), and the Japanese policy framework for a Sound Material Cycle Society REF which includes a set of material flow-related targets including material productivity of the economy, the recycling rate, and the amount of final waste disposal (Takiguchi and Takemoto, 2008).

The economic context for material use has changed profoundly. Economic development in the twentieth century was fueled by affordable natural resources, and prices were declining during most of the century. Since 2000, the price of most natural resources has been rising and price volatility has increased because of the vast resource demand of many developing economies, especially China, and supply capacities have fallen behind demand. In this new economic context, national governments and business leaders require an extended set of information for decision making beyond monetary economic indicators. Material flow accounts and indicators provide this information.

Materiality and Culture

Stuart McLean, University of Minnesota, Minneapolis, MN, USA

Abstract

'Materiality' and 'culture' are among the most discussed terms in contemporary social and cultural theory. This article offers a broad introductory overview of current debates both within the discipline of anthropology and beyond and situates these briefly with reference to anthropology's and social thought's entanglements with longer-term histories of, for example, capitalism and European colonial expansion.

How might we begin to describe and understand the relationship of collective life to the material universe in which it unfolds? How is the materiality of, for example, bodies, artifacts, and environments implicated in formations of power, identity, and belonging? Is the material world significant only insofar as it is interpreted and represented by humans, or should we think of matter as an autonomous power, possessed of its own determinations and agentive capacities and thus as capable of intervening in human affairs in ways that challenge or refuse social scientific explanation?

The terms 'materiality' and 'culture' have been the subject of some of the most intense and wide-ranging debates in contemporary social and cultural theory, drawing on a broad range of intellectual influences, including Marxism, structuralism and semiotics, philosophy, human geography, biology, and physics (Coole and Frost, 2010; Dolphijn and van der Tuin, 2012). In anthropology, a renewed attentiveness to the material world has been fostered too by, among other things, science studies, especially the approach some times referred to as Actor Network Theory, with its call to include other-than-human presences and agencies in accounts of social life, a call to which contemporary ecological crises are seen as lending a new urgency (Latour, 1993, 2013). At the same time, anthropological theorizing developed on the basis of ethnographic research conducted in (predominantly) non-Western contexts, notably Melanesia, has drawn attention to the variety of ways in which humans and material things are interconnected, suggesting the possibility of understanding personhood and agency as 'fractal' or 'distributed' (composed of relationships extending across time and space) rather than simply individuated (Gell, 1998; Strathern, 1988; Wagner, 1991). There remain, however, profound disagreements among many of the parties to these discussions. Indeed, it may be that 'culture' and 'materiality' necessarily exist in a relationship of tension. On the one hand, the concept of 'culture' in anthropology has often been understood as that which defines the distinctiveness of humans as a species, as well as the differences among human groups, whether this is understood (for example) with reference to language, to the use of symbols more generally, or to the broad array of beliefs, values, and behaviors that, according to Tylor, humans acquired by virtue of their participation in a social group (Kroeber and Kluckhohn, 1952; Tylor, 1903). 'Materiality,' of course, can be taken as referring either to particular material things or to the material being of the world in general. As such, it might be understood as pertaining not to what sets humans apart but to what they share inescapably both with other life forms and with material entities of all kinds. For example, the human beings who, as culture-bearers, have featured as anthropology's self-designated object of study lead lives that are inextricably entangled with a variety of material worldly presences. These might include, on the one hand, features of the physical environment such as trees, rivers, mountains, oceans, or a range of humanly manufactured artifacts, including cooking utensils, items of clothing, buildings, ritual objects, automobiles, computers, and cell phones. At the same time, human beings are themselves material entities, that is, bodies composed of cells and molecules. As such, they eat, drink, sweat, urinate and defecate, fall sick, become sexually aroused, grow old, and eventually die and decompose, whereupon their constituent substance is redistributed and recombined with that of their surroundings. Materiality and culture are, therefore, neither straightforwardly identical nor unambiguously distinct. Rather, they remain for anthropology inextricably yet unresolvedly entangled.

Despite this seeming centrality to anthropology's self-designated subject matter, however, it has often been suggested that materiality has emerged only in recent decades as a focus of sustained anthropological inquiry. Certainly, the period since the 1980s has witnessed a striking proliferation of works of anthropological scholarship specifically focused on aspects of the material world, from fashion to communication technologies to home decoration. Yet, this rapid expansion of interest can be contrasted with a relative lack of interest on anthropology's part throughout most of the twentieth century in the variegated materialities of social life. This lack of interest has sometimes been explained with reference to the divisions between 'Mind' and 'Matter' or between 'Nature' on the one hand and 'Society' or 'Culture' on the other that have often been taken to characterize modern, Western thought. Some commentators have suggested that these dualisms can be traced to the so-called 'scientific revolution' in seventeenth-century Europe and the resultant division of academic labor between the natural sciences on the one hand and the social sciences on the other (Latour, 1993; Shapin and Schaffer, 1985). Others have drawn attention to the influence of the protestant Reformation's denial of the efficacy of religious relics and the reality of transubstantiation as a repudiation of the agency of material things and their relegation to a more passive role as

bearers of humanly assigned 'symbolic' meanings (Keane, 2007). Yet others have suggested that anthropology's longstanding disinclination to engage materiality on its own terms must be traced back further to the beginnings of Western thought, in particular to the overturning of pre-Socratic cosmologies (like that of Heraclitus of Ephesus) based on material flows and transformations with a new emphasis on intelligible form as the basis of identity, knowledge, and classification, the latter view finding one of its most influential expressions in Aristotle's Physics, where it is argued that acts of creation, of making, involve precisely the imposition of form, *morphe*, on inchoate matter, *hyle* (Harrison, 1993; Ingold, 2011). These different periodizations nonetheless concur in seeing anthropology's neglect of the material world as symptomatic of a more long-standing and deep-seated Western intellectual prejudice and in arguing for a contemporary reengagement with materiality as a way of overcoming this. Indeed, a number of commentators have noted that recent work in material culture studies has often echoed the idioms of postcolonial theory in arguing for the 'emancipation' of material things from what is seen as a hitherto one-sided emphasis on culture, history, society, or the human subject (Fowles, 2010). Many contemporary debates about the status of material things and processes can be understood as centering precisely on the degree to which different conceptual and methodological approaches can be seen to have succeeded in achieving such an emancipation by supplanting the entrenched dichotomies of nature and culture and mind and matter against which such a project is staked.

Nonetheless, contemporary anthropology's awakened interest in materiality is not without historical precedents. Indeed, the emergence of anthropology as a discipline is, arguably, closely intertwined with the transformations of the material world brought about by the parallel histories of European colonial expansion and the development of industrial capitalism. For example, the nineteenth-century heyday of European imperialism that coincided with the beginnings of anthropology as an academic discipline also witnessed the influx into Europe and North America of quantities of non-Western artifacts from Europe's onetime colonies. These in turn came to form the basis of major ethnographic collections, like those of the Museum of Natural History (New York), the British Museum (London), the Pitt-Rivers Museum (Oxford), the Musée de l'Homme (Paris), the Ethnological Museum (Berlin), or the Russian Museum of Ethnography (St. Petersburg) and were extensively discussed in the writings of many of the founding figures of anthropology, like Franz Boas (Boas, 1983). Many of these same artifacts, exhibited in museums or sold in the open market would prove to be a source of inspiration for pioneers of artistic modernism like Braque and Picasso. As such, they would also facilitate a sharing of influences between anthropology early twentieth-century literary and artistic avant-gardes, as in Paris in the 1920s and 1930s. The resultant moment of 'ethnographic surrealism' (as James Clifford would later describe it) was one that brought together anthropologists like Alfred Métraux, Marcel Griaule, and the young Clause Lévi-Strauss and figures on the fringes of the Surrealist movement like Georges Bataille, in part on the basis of a shared curiosity about material artifacts (Clifford, 1981; Wilcken, 2010). It was this same milieu that also produced one of the classic works of economic anthropology, Marcel Mauss's Essay on the Gift (1925) a work exploring the mutual entanglement of human persons and objects of ritual exchange (mainly in the context of Pacific island societies) and often cited as an important influence on contemporary material culture studies (Mauss, 2000). The focus on artifacts characteristic of much of the nineteenth and early twentieth-century anthropology was, nonetheless, to a large degree displaced from the 1920s onward by the rise of fieldwork-based anthropology and, in particular, the approaches known as functionalism and structural functionalism. Rather than being treated as a potential source of cultural insights (as in the writings of Boas and others) material objects were often henceforward to be relegated to a merely utilitarian significance or else disregarded altogether in pursuit of more abstractly conceived understandings of social structure (Tilley et al., 2006a,b). More recent scholarship, however, has sometimes returned to reconsider the fate of colonial era and later artifacts and the transformations to which they were subject in traversing the different contexts of, for example, religious or ritual use, commercial exchange and display in museums or galleries (e.g., Thomas, 1991; Price, 1989).

Another important antecedent of present-day material culture studies is to be found in the writings of Karl Marx. Marx's influence on the social sciences is a varied and wide-ranging one (Bloch, 2010; Diamond, 1979). Nonetheless, two aspects of his work in particular seem especially pertinent to contemporary engagements with materiality and culture. The first of these is the version of materialism (sometimes referred to as 'historical materialism') that Marx developed through his engagements with the philosophical legacy of Hegel on the one hand and the history and political economy of industrial capitalism on the other. Marx's materialism was one that emphasized productive human activity and sought to understand social institutions and forms of consciousness on the basis of their derivation from modes of human interaction with the material world. In this respect, he distinguishes his own approach from what he takes to be the passive or 'contemplative' materialism of contemporaries like Feuerbach (Marx, 1978). Marx's writings are, therefore, concerned primarily with the productive transformation of materials by human labor rather than with the ontological status of materials themselves or the possibility that they might lead a life independent of the humans who make use of them. A second aspect of Marx's thought that is frequently referenced in contemporary debates about materiality and culture is his discussion of the fate of humanly manufactured objects under capitalist conditions of production. One aspect of the alienation experienced by workers under capitalism in Marx's view consists in their inability to recognize themselves in the products of their own labor, which are appropriated and sold for a profit by the owners of the means of production. Under capitalism, Marx suggests, objects are, increasingly, produced as commodities. That is, they are produced in order to be transferred to others by way of market exchange and to derive their 'exchange value' precisely from their relation to other commodities and

to the money form as a universal equivalent capable of expressing the market values of diverse products. In this respect, Marx's principal interest is, arguably, in what commodities have in common with each other as objects to be exchanged. Consideration of the sensuous particularity of objects is, rather, reserved for the discussion of 'use values' – that is, of the capacity of particular things to meet particular needs on the basis of their specific material properties. In contrast, later ethnographic studies of the social life of commodities have often introduced more extended consideration of the material and symbolic differences between different kinds of objects of exchange. Sometimes this has meant focusing on a particular commodity and its movement through an emerging capitalist world system (Mintz, 1986). Sometimes it has involved exploring the ways in which particular objects can be understood as shifting in and out of commodity status, for example, by being, bought, resold, given as gifts or incorporated into private collections, making it possible, so the argument goes, to consider gift-based and commodity-based economies as potentially contemporaneous and coexistent rather than successive moments of a linear historical teleology (Appadurai, 1988).

In recent decades, such a shift of emphasis from production to consumption has also been characteristic of much work done under the name of the interdisciplinary field of material culture studies, the development and rapid expansion of which is attested by the establishment of specialized academic programs, like the one at University College London and specialized publications, like the *Journal of Material Culture* (edited out of UCL and founded in 1996). Material culture studies is, however, a wide-ranging and heterogeneous field, practitioners of which have, at various times, defined themselves in terms both of breaks from and continuities with anthropology's past, acknowledging some antecedents (including Mauss and late nineteenth and early twentieth-century studies of ethnographic artifacts), while pointedly disavowing others. Structuralist influenced approaches, for instance, had previously sought to extend consideration of the social meaning of manufactured objects by locating them in a larger system of relations from which their individual significances are understood to derive. Lévi-Strauss himself collected quantities of indigenous artifacts during his fieldwork in Brazil (1935–39) and criticized functionalist approaches like that of Malinowski for their neglect of material culture. Several of Lévi-Strauss's own published works were devoted to the analysis of material artifacts, for example his study of the Northwest Coast Native American masks that he first encountered in New York's Museum of Natural History (Lévi-Strauss, 1982; Wilcken, 2010). From the 1960s onward, Lévi-Strauss's writings would in turn influence a number of studies of the consumer culture of Western, capitalist societies, such as Roland Barthes account of the 'fashion system' (Barthes, 1990). Nonetheless, despite obvious commonalities of subject matter, more recent work in material culture studies has often been explicitly critical of structuralist approaches, not least for their indebtedness to the linguistic theories of Ferdinand de Saussure (1885–1913). In particular, structuralistic accounts of material objects have been criticized for their emphasis on symbolic meaning as a relational effect of disembodied sign systems and their consequent neglect of the material specificities of the objects under consideration (Saussure, 1998). Webb Keane, for example, argues that Saussure's understanding of the linguistic sign, with its insistence on the arbitrary and conventional relationship between signifiers and signifieds, represents a version of what Bruno Latour has called the work of 'purification,' reflecting a characteristically modernistic desire to definitively separate meanings and materialities, humans, and nonhumans, to be accomplished in part by denying the agency of material things. Keane criticizes such a separation as being expressive of a characteristically modern, Western 'semiotic ideology.' Instead, he argues for a view of material objects as existing radically independently of human interpretations and actions and, therefore, capable of intervening on human affairs to unforeseen and surprising effect. As an alternative to Saussure, he proposes a renewed engagement with the semiotic theories of the American philosopher Charles Sanders Peirce (1839–1914), including the latter's insistence on the nonarbitrary relationship of certain signs to their referents, notably icons and indices, understood as linked to their referents on the basis of resemblance and physical contiguity, respectively (Keane, 2007; Latour, 1993; Peirce, 2011).

Alfred Gell too, in his widely cited *Art and Agency*, explicitly rejects the extension of Saussure's formulation of the 'arbitrary nature of the sign' into material culture studies on the grounds that such a move represents an 'over generalization of linguistic semiotics.' Developing a theory of art based not on aesthetics but on an analysis of the effects that artworks can be seen to produce, Gell argues, famously, that material things as well as human subjects can be understood as possessing agency not only insofar as they produce worldly effects but also because they can be viewed on that basis as indexing a prior intention to produce such effects (Gell, 1998). Subsequent commentators on Gell's work, however, have often expressed doubt as to the degree to which his account does, in fact, grant agency to material things in their own right. James Leach, for example, suggests that, for Gell, the intentions indexed by things are, ultimately, human ones, while Daniel Miller, another influential contemporary theorist of material culture, characterizes Gell's theory or art as one of 'natural anthropomorphism' in which the primary point of reference remains the humans behind the artifacts (Leach, 2007; Miller, 2005). Miller himself emphasizes rather the interactions between subjects and objects and the ways in which they can be understood to reciprocally constitute one another. In a series of studies of shopping and consumption, Miller invokes not Marx but Hegel to argue that such practices can be understood in terms of the externalization of human powers and intentions in the guise of institutions like the economy and the overcoming of such alienation through practices of consumption. In this respect, Miller differs from a number of other contemporary commentators on Marx and Hegel, notably the philosopher Slavoj Žižek, for whom Marx's historical materialism remains definitively grounded in the thought of Hegel (Žižek, 2013). Instead, rejecting Marx's vision of revolutionary change, Miller argues that this two-way movement of the externalization and reappropriation of human powers is a continuous and open-ended process rather something that will, eventually, be definitively resolved through the revolutionary transformation of capitalist relations of production (Miller, 2001). Miller's emphasis on the human appropriation

of material objects has been criticized by his colleague Christopher Pinney, who argues for an engagement with materiality beyond the assumed complementarity of subject and object and the human-centered understandings of context and history that have tended to go with it. Instead, Pinney invokes the work of two thinkers associated with the Marxist-influenced Frankfurt School, Theodor Adorno and Siegfried Kracauer (who, in his later writings, draws explicitly on the work of Lévi-Strauss) to argue for a 'nonhomogeneity' of time and an excess or 'torque' of materiality that can never be fully assimilated to the closure of 'culture' or 'history' (Pinney, 2005).

Another influential current in contemporary material culture studies has called upon the resources of phenomenology to explore the varieties of human sensory engagement in the material world. Drawing upon the philosophical work of, among others, Husserl, Heidegger, and Merleau-Ponty, such approaches seek to overcome received dualisms of mind and matter by taking as their starting point the experience of a human subject understood as always already embodied in the world. This approach has proven particularly fruitful in studies relating to landscape, like those of the British archaeologist Christopher Tilley, who has drawn on phenomenological literature to explore sensorial engagements with archaeological sites, particularly prehistoric structures where there are no supporting documentary sources to provide access to the intentions or cultural self-understandings of builders, occupants, and users. Instead, Tilley suggests that the sensing body can provide important clues to the interpretation of such sites by way of, for example, the experiential contrast between open and closed spaces or the mutual visibility of built structures within a particular landscape (Tilley, 1994, 2004).

However, if the burgeoning interdisciplinary field of material culture studies has been an exceptionally productive one in recent decades, it should also be emphasized that the range of approaches it represents does not by any means exhaust contemporary discussions of materiality and culture. For example, despite the emphasis of much phenemenologically inspired work in material culture studies on sensory experience as a way of dispensing with assumed distinctions between subjects and objects, this has often entailed little or no sustained engagement with the ways in which the biological and cognitive sciences have sought to understand the sensing body as a material entity. Indeed, phenomenological perspectives have sometimes been criticized by scholars working outside the field of material culture studies for presenting themselves as a more empathetic and humanistic alternative to the supposed reductionism of scientific accounts of the body and thus as failing to acknowledge or respond to the intellectual challenges that the latter might be seen to pose (Colebrook, 2010). It is worth noting, however, that a number of anthropologists influenced by phenomenology have recently begun to engage more explicitly with current research in the neurological and physiological sciences (e.g., Downey and Lende, 2013; Marchand, 2010).

Among anthropologists Tim Ingold has criticized material culture studies both for failing to overcome the separation of material realities and mental representations (continuing to treat them rather as distinct realms that need to be brought into relation through the work of analysis) and for its predilection for the study of readymade artifacts such as consumer objects rather than processes of making. Closer attention to such processes, he suggests, might yield an approach to the material world based not on discrete objects and the collective or personal significances with which they are supposedly endowed, but rather on material substances and their transformations, whether at the hands of human artists or craftspersons or through the actions of other than human agents such as meteorological processes. The term 'materiality' is, Ingold suggests, "too abstract to adequately convey the density, dynamism and variousness of materials, which are," he argues, "better understood with reference to a more expansively conceived ecology of 'life' encompassing a range of human and other than human presences" (Ingold, 2011). Ingold's arguments have been echoed more recently by Eduardo Kohn, in calling for an 'anthropology beyond the human' addressed to an 'ecology of selves' encompassing not only human subjects but also animals, plants, spirits, and entities of other kinds. Like Keane, Kohn suggests that, rather than Saussurean linguistics, Peircean semiotics, with its openness to semiotic modalities other than the symbolic, may be a more suggestive basis for engaging the nonhuman world (Kohn, 2013).

Thinkers seeking an alternative to phenomenology's emphasis on a sensing, experiencing human subject have often found inspiration in the work of the philosopher Gilles Deleuze (including his collaborations with the activist and psychoanalyst Félix Guattari). Deleuze's prioritization of becoming and the impersonal movement of 'A Life' of which both subjectivity and the individuated organism are understood as transitory products have proved suggestive not least in their traversing of familiar distinctions between the human and the nonhuman, the material and the ideal, the theoretical and the practical and have exercised a direct influence on, for example, Latour and Ingold. At the same time, Deleuze's commitment to the irreducibility of difference, refusing any appeal to transcendence or a hierarchy of being, combined with his insistence on the reality of concepts and the imperative to continuously create new ones offers, arguably, a strong provocation to rethink the terms on which anthropology engages with other humans and nonhumans (Deleuze, 1994, 2001; Jensen and Rödje 2010). In this respect, Deleuze's thought has been a significant influence on what has sometimes been called the 'ontological turn' in recent anthropological theory, along with the work of, among others, Marilyn Strathern (United Kingdom), Roy Wagner (United States), and Eduardo Viveiros de Castro (Brazil). Rejecting what they take to be a false and parochially Western distinction between a material world understood as given (or 'nature') and different peoples' variegated representations of it ('culture'), anthropologists associated with the ontological turn have argued for the need to 'take seriously' the concepts generated by the people anthropologists study. Rather than treating such concepts as representations (or misrepresentations) of a world assumed to be external to them, they argue (like Deleuze) that such concepts are efficacious worldly entities that contribute to the production of particular realities. One of the most sustained applications of this approach to the study of the material world is to be found in the volume *Thinking through Things* (Henare et al., 2007). Although referencing Latour's

account of the simultaneously purifying and hybridizing work of the 'modern constitution,' contributors to the volume also distance themselves from Latour's own universalizing ontological claims regarding the ubiquity of networks by arguing for a plurality of ontologies and for a methodology of anthropological engagement with the material world that might allow these to emerge. Rather than appealing to assumed social or cultural 'contexts' as a basis for understanding material artifacts and their implications in collective life, they suggest that the ethnographic study of 'things' (a term preferred to the allegedly more theoretically laden 'objects') might allow the latter to dictate the terms of their own analysis. Hence, for example, Martin Holbraad's account of the *aché* powder that Cuban *Ifá* diviners both use and talk about as constituting their divinatory power argues that *aché* should be understood as presenting a challenge to anthropology to revise its own theoretical lexicon by moving beyond the assumed Western opposition between concepts and things insofar as *aché* powder is simultaneously and irreducibly both a material substance and a power of divination (Holbraad, 2007). In a more recent essay, Holbraad argues that his earlier approach does not go far enough, concentrating as it does on the diviners' own definitions of *aché* rather than on the material qualities of the power itself (e.g., its motility and particulate composition) as directly informing its conceptualizations by its human users (Holbraad, 2011).

If the ontological turn argues for an understanding of materiality and artifactuality as variously emergent within different ontologies and world-making projects, other approaches have sought to depart from representational thinking by emphasizing the material world as a presence that potentially exceeds and disrupts human understandings of it. Jane Bennett, for example, has argued for a 'vital' materialism refusing any clear-cut separation between 'inert' matter and life. Drawing eclectically on science studies, complexity theory, and the philosophies of Spinoza, Nietzsche, and Deleuze, Bennett envisions a world in continuous becoming, populated by heterogeneous entities that are themselves emergent within the differentiating, world-forming flows of a single matter energy. A sensitivity to and an appreciation of the vitality of matter, she suggests, has potential political consequences insofar as it is likely, for example, to deter destructive and purely instrumental human engagements with the natural environment. At the same time (and in contrast to some phenomenologically inspired work) Bennett urges scholars in humanities and social sciences to pay closer attention to the new accounts of the material world being produced by the contemporary sciences, readings of literary, philosophical, and other texts being interspersed in her work with discussions of recent developments in fields such as evolutionary biology and nanotechnology (Bennett, 2001, 2010).

If one of Bennett's stated aims is to promote more sensitive and sustainable human engagements with the material world, other recent theorists have elaborated a vision of materiality as more radically autonomous of and indifferent to human projects and purposes. An important influence here has been the work of Georges Bataille (1897–1962), whose writings ranged over anthropology, economics, literature, and surrealism. Like some more recent and canonical theorists of material culture, Bataille draws upon the writings of Hegel, but does so not in order to resolve the dualism of mind or spirit and matter but to insist upon and accentuate it. Bataille's reading of Hegel (influenced in turn by the lectures of the Russian émigré Alexander Kojève) emphasizes not Spirit's cumulative realization of its own freedom but rather the unsurpassability of the negative, which Bataille identifies specifically as an autonomous power of matter, reasserting itself continually in the face of humanity's efforts to transcend it and as such suggesting the possibility of a 'virulent materialism' not subservient to any higher, 'spiritual' authority. Bataille's work can be understood as a series of attempts to articulate this power of matter through a variety of genres and media, including experimental essays, pseudonymously published pornographic fictions, reflections on Aztec human sacrifice, and European prehistoric art and through his uncompleted trilogy *The Accursed Share*, in which he sets out an alternative science of political economy (a 'General Economy') founded not upon assumed scarcity but on excess, expenditure, and the prodigality of matter-energy, understood as manifesting itself in the guise of superabundance if considered on a planetary or cosmic scale rather than a 'restricted' human one (Bataille, 1985, 1988; Kojève, 1980).

In the decades, since his death, Bataille's writings have proved intermittently influential in anthropology as in other fields, for example the work of the British philosopher Nick Land, who emphasizes the militantly antihumanist character of Bataille's project (e.g., Taussig, 1995; Ochoa, 2010; Land, 1991). More recently, Bataille (and Land's account of him) has been the subject of renewed attention by the philosophers and theorists associated with what has sometimes been called speculative materialism or speculative realism. The latter, encompassing a topically and stylistically diverse range of projects, has been characterized by an insistence on the imperative to think and describe a world understood as existing radically independently of its being given to a knowing, perceiving human subject. For example, the 'theory fiction' practiced by the (now US-based) Iranian thinker Reza Negarestani echoes Bataille's fictions and literary essays by splicing together narrative and philosophical reflection to evoke a vision of the contemporary Middle East and the oil that flows from its subterranean depths as animate, sentient entities, capable of interfering in a variety of ways with projects of human history-making (Negarestani, 2008). Quentin Meillasoux, meanwhile, avails of a more conventionally philosophical idiom to argue both for a renewed engagement with what he terms the 'ancestral' or the 'Great Outdoors' – that is, with a material world understood as existing prior to and autonomously of human thought and perception. The sciences, he suggests – in particular evolutionary biology and geology – present a challenge to philosophy precisely because they purport to describe such a world, making reference to events such as the emergence of terrestrial life that necessarily predate human subjectivity and, thus, the possibility of philosophical reflection (Meillasoux, 2009). In contrast, the work of Graham Harman, who has been credited with coining the phrase 'object-oriented philosophy' (or ontology), has been characterized by a closer and more sustained engagement with objects as such, which, for Harman, are not necessarily material artifacts but can comprise a variety of other entities, including philosophical movements. Indeed, Harman, has been explicitly critical of the writings of Deleuze and those influenced by him for dissolving the density and

opacity of objects into what they assume to be an underlying flux of becoming and of Latour's actor-network theory for subordinating objects to the relations that supposedly constitute them (Harman, 2009). Instead, Harman argues that objects are characterized by their capacity both to withdraw from engagement with humans and with each other and to enter into relations with one another without reliance on any mediating human presence (Harman, 2002). Harman, in turn, has been criticized by the literary scholar and cultural theorist Steven Shaviro for failing to provide a persuasive account of change, in particular of how objects (of what ever kind) come into existence (Shaviro, 2011). It is perhaps speculative materialism's rejection of the view that the material world is inescapably mediated by a human subject, language or culture that presents the greatest challenge to anthropology. Indeed, what Meillasoux, Harman, and others ask us to entertain is, precisely, the possibility of a world without humans. As a result, perhaps (and despite the wider currency their work has attained in other fields such as cultural geography and philosophy), many of these thinkers have been only occasionally cited in recent anthropological literature (e.g., McLean, 2013), although the work of Harman (including his book length study of Bruno Latour) has attracted attention in science studies and archaeology (e.g., Graves-Brown et al., 2013). Nonetheless, the debates initiated by speculative realism seem likely to have a significant influence on future research and writing.

The above inevitably represents a selective sampling of past and present debates rather than a comprehensive overview. It should be apparent nonetheless that discussions of materiality and culture encompass a broad, heterogeneous, and often fiercely contested terrain, on which a variety of methodologies and theoretical perspectives have been brought to bear. If the relationship between materiality and culture remains central to anthropology's understandings both of its subject matter and of itself as an academic discipline, it is a relationship that can perhaps never be definitively resolved, but is likely to remain rather a productive source of tensions and disagreements. Materiality, considered in relation to culture offers not the reassurance of a ground or a refuge of certitude but a constant source of new questions – questions that are of fundamental importance not only to the theory and practice of anthropology but also, more broadly, to human beings' understanding of themselves, their place in the world, and the relations they maintain with other entities of all kinds.

Abstract

Approaches to acquiring comprehension of mathematical concepts and the linked ability of reasoning differ across history and culture. Research shows that a process view should be preferred to the more widely spread object view in order to benefit the formation of sustainable early mathematical concepts. Opportunities for cognitive development in the context of early mathematics education are among other things facilitated by mathematical playworlds that take the broad mathematical background seriously. The multifarious uses and possible resulting benefits of action-based mathematical playworlds are displayed within this contribution.

Introduction

Mathematics is basically about mathematical truths outlasting time. Mathematical concepts should fit together smoothly; furthermore mathematical truth needs reasoning: reasoning tools and reasoning objects. Everyday life does not tell much about mathematics unless one starts thinking mathematically. Look at the diagonal's length d of a square with the given length of s on each side (Figure 1).

There is no way to see, read off, or directly guess either the precise length of d in terms of numbers (the word 'number' refers to natural numbers) or the numerical relationship between d and s. Successful mathematical reasoning may lead to a mathematical equation, and in case of a specific number for s to a mathematical numerical value. Given $s = 1$ cm the number in question is something close to 1.4142135623730950488016887242096 98 with even more, actually an endless, number of digits to follow after the last 8. In fact, applying the well-known theorem of Pythagoras, which goes back for thousands of years, and using the knowledge about irrational numbers, which emerged only much later the argumentation easily follows: $d = \sqrt{2}$ cm.

The central question is, How to introduce early mathematical ideas to young children so that early mathematical reasoning is actually involved? Figure 2 shows a well-known approach for preschoolers to deal with a number setting. Obviously, without adult guidance focusing on numerical relations true mathematical understanding is unlikely to emerge. In order to reach this goal the use of special material suggests itself. Fortunately, mathematics is rule based. Rules are also part of games. One promising approach to our question is developing suitable mathematical playworlds. (Mathematical playworlds: Various action-based games strongly related to mathematical concepts used in early mathematical education in order to enhance the mathematical reasoning and comprehension as well as the cognitive capacity of children.) Thereby it is possible to demonstrate mathematical ideas and their relationships in a way everyday objects cannot achieve. Sticking to the rules or exploring what is happening when rules are changed is also part of nonmathematical games as a natural process of socialization.

Figure 1 Given the length s in a square, what length is d? Also think of it in case of $s = 1$ cm.

Figure 2 Preschooler arranges beads on poles in a configuration from left 1 to right 10 beads.

Development of Mathematical Reasoning

Little is yet known about the development of mathematical reasoning. It is largely considered progressive to examine the so-called mental number line within various contexts. Investigating the interaction of language and cognition is widely spread, also in case of numerical cognition. Bender and Beller even go as far as to assume that "there may be no other domain in the field of cognitive sciences where it is so obvious that language (i.e., the verbal numeration system) affects cognition (i.e., mental arithmetic)" (2008: 215; see also Bender and Beller, 2011). Accordingly, investigating the link between the different cognitive tools used as number words and the underlying mathematical comprehension can be considered especially insightful.

It is often regarded reasonable to exert influence on children in a way that they first develop the number word sequence and learn counting afterward. Also, the five counting principles (Gelman and Gallistel, 1978) are often referred to. However, they lack in emphasizing the special significance of counting being particularly about managing numeric relations within a number space. The works of Starkey et al. point out that the focus in early childhood mathematics should be on building on the informal mathematical knowledge by creating, inviting situations within the framework of kindergarten/preschool and parental care instead of emphasizing formal knowledge too early (Starkey and Cooper, 1980; Starkey and Klein, 2008).

Predicative- and Functional-Logical Reasoning

Our long-term research about the development of mathematical thinking includes examining some basic principles of logical thinking. In this regard we adopted one of Spearman's task formats (Spearman, 1904) and specified it in terms of two different types of inferential logical reasoning:

- Predicative-logical reasoning: A type of inferential logical thinking that establishes relations by focusing on similar or identical components of objects.
- Functional-logical reasoning: A type of inferential logical thinking that establishes relations by thinking in action sequences and achievable effects by means of what differences in objects can be converted into one another.

Depending on the way of thinking the orientation in the world, types of basic sources for getting insight and construction of a world view are not the same.

Let us examine one of our matrices (Figure 3): In the bottom right corner there is a figure missing. Which one might fit in? Why?

Cognitive procedures allow establishing relations between the figures: specific figure components come to the fore while other components remain apparitional.

Mental Constructions with Accents

Predicative-logical reasoning establishes relationships by focusing on similar or identical components. Concerning the given task, in the first row the upper and lower lines 'belong together' but the side lines do not fit the pattern (Figure 4). This categorization generates order and structure. Continuing this cognitive appraisal results in a figure with lines from the bottom row (upper and lower) and the right-hand column (sides) respectively.

Figure 3 Task example from the Qualitative Diagnostic Instrument for Predicative-logical vs Functional-logical Thinking (QuaDiPF).

Figure 4 Mental construction with Predicative-logical focus.

Functional-logical reasoning establishes relations by thinking in action sequences and achievable effects by means of which differences can be transformed into one another (Figure 5). Concerning the given task, in the first row the side lines can be pulled inward and subsequently outward. This mentally creates a dynamic view of alterable figures. Continuing this cognitive appraisal results in a figure with the upper, lower, and side lines pulled outward. Actor-bound reasoning is required in order to produce result figures (Figure 6).

Figure 5 Mental construction with Functional-logical focus.

Figure 6 Importance of action-oriented reasoning in case of Functional-logical thinking.

In the context of two PhD projects, one run in Indonesia by Marpaung and the other in China by Xu, it turned out that predicative-logical and functional-logical approaches also occur in non-Western cultures (see e.g., Schwank, 1999, 2003).

In line with findings from psychological studies including several differing approaches and experimental setups (e.g., Kimura, 2000; Ceci and Williams, 2007), findings of our research show more boys scoring higher in functional-logical reasoning than girls. In early mathematical education which is strongly coined by arithmetical content, these differences in logic-based orientation should be kept in mind. Calculating means handling numbers. Numbers are being changed during calculating. Being able to understand numbers as arising from calculation processes is beneficial.

Reference Systems – M^4-Model

Interrelations play an important role. How ideas are generated is not clear yet, but reference systems seem to hold a key role since ancient times. One example for such a reference system is language. Another example is specific technology, invented by mankind for certain events.

Due to their innate nature technological systems can be used for tackling other problems while their originally intended purpose retreats to the background.

Let us have a look at the following example:

> Bells in China go back about 5,000 years. … [Particular bells] would once have been part of a set of either nine or fourteen. Each would have been a different size, and would produce two different tones, depending on where it was struck [from the outside with a hammer]. … But the role of bells in China could go far beyond the musical. To produce perfect tones they had to have absolutely standardized shapes, and the consistency of these shapes meant that the bells could also be used to measure standard volumes. And as the amount of bronze in each one was also carefully controlled, they could just as well provide standard weights. So a set of bells in ancient China could also serve as a sort of local weights and measures office, bringing harmony to commerce as well as society. (MacGregor, 2010: 193)

At first the goal was producing sounds with hollow articles based on the new technology of bronze work (Figure 7: Bronze Yong Bell).

The importance in this undertaking lay not so much in the individual sound as in the perfect harmonization of the various sounds generated by different bells. By succeeding in this task a system allowing a perfect attunement between the individual elements was developed which could then be used for other tasks like measuring volume or weight.

Using this normative structure it became possible to handle more precise indications of size, e.g., this volume is twice as much as that, this weight is four times as much as that one. The mentally possible continuation of building bells allows applying the bells' relations to situations for which actual bells could never have been built. The idea of manufacturability and thus usability of many further bells permits mentally reaching beyond reality. The sizes and their relations become elements of thought no longer relying on existing bells. However, the generated idea of construction originates from the original universe of bells. Therefore the system of bells is both source and root of this mental construction and consequently inseparably associated with it.

Figure 7 Chinese Bronze Yong Bell.

The basic idea of using reference systems can also be introduced into early mathematics education. The M^4-Model displays important structural connections (Figure 8). Initially, neither mathematical symbols nor mathematical terminology is known to the learner. The point is to generate mathematical ideas, made possible by dealing with mathematical idea-related events. This most important connection between these compartments is highlighted in purple within the model. Thereby these events should be envisioned just like the bells used in the example above.

Figure 8 M^4-Model.

Preschoolers' gaining of mathematical insight is substantially dependent on to what extent the mathematical playworlds provided as cognitive stimulation actually contain mathematical elements. There is a lack of appreciation for playworlds developing mathematical thinking. The fundamental experience of relating things to one another – e.g., by means of number-related events – is of great importance to foster mathematical-logical thinking and reasoning. We assume this to be a formative fundamental experience that profoundly contributes to handling mathematics with pleasure.

Understanding Numbers

N^4-Model

Breaking the M^4-Model down into the number world results in the N^4-Model (Figure 9). (Based on Dehaene's triple-code model, the following four interacting compartments are displayed: number ideas, number symbols, number terminology, and number idea-related events. To do the requirements of mathematics education justice, the connection number ideas–number idea-related events is of major significance in the field of early childhood mathematics.)

The N^4-Model resembles Dehaene's triple-code model (1992). 'Number symbols' and 'number terminology' match Dehaene's 'visual Arabic number form' and 'auditory verbal word frame' but as opposed to Dehaene's "analogue magnitude representation" here 'number ideas' are suggested. Numbers and their multifarious relations are of great importance in terms of construction principles. Therefore, ideas or ways to arrange number relations are needed. The main difference is the addition of a fourth compartment: the 'number idea-related events' that is connected to the number ideas (connection marked in purple).

Figure 9 N^4-Model.

Internal and External Representation of Numbers

Number ideas express that numbers are mental constructions. Numbers cannot be seen or touched. Internal and external representations of numbers are necessary. Number terminology and number symbols form a part of these representations. The meaningfulness begins with analyzing the number idea-related events.

Number Terminology–Number Words

When jumping a couple of times or placing objects on a table saying 'one, two, three, …' number names are used in communication – the focus being on numerosity. There are huge differences among history and culture as to which words emerge and are used for numerical contexts (e.g., Ifrah, 1998). Presumably the starting point was the development of expressions not containing basic counting principles such as both, couple, pair, brace, score, gross, several, some, any, and so forth, depending on the specific situation within different cultures and languages.

Number Symbols

The success of mathematics is closely linked to the fact that mathematicians invent their own language to communicate about their newly conceptualized and deeply elaborated mathematical objects. Throughout the millennia people succeeded in developing a sign system for numbers facilitating symbolic calculation: the decimal place-value system. Due to the decimal system's inbuilt functionality only the 10 numerals 0–9 are needed to display any of the infinite numbers.

Fundamental Number Meaning

The significance of all, not only natural numbers, is undoubted (e.g., Dantzig, 1930; Brainerd, 1979). The scientific explanation of what the so naturally seeming numbers are about occurred at a relatively late point in mathematical history (e.g., Dedekind, 1969/1887).

As a matter of fact, every number itself is the result of a calculation. The basic meaning of a number is how often it has been counted forward by one, starting with zero, e.g.,

$$0 + 1 + 1 + 1 = 3 \quad \text{or} \quad 0 + 1 + 1 + 1 + 1 = 4$$

It should be beard in mind that it is not the number of 'ones'/'1' that count but the number of 'counting forward'/'+1.'

The key role in learning to understand numbers is not so much taken on by static situations than by dynamic events. Using not only number word sequences and especially not doing so too early would be beneficial in early childhood mathematics. The emphasis should be on cases of repetition. Therefore, simple verbalizations are needed for events such as something being added, e.g., 'one more, one more, one more.' The importance of a linguistic attendance of early mathematical concept formation certainly needs to be further elaborated.

Proper Names–Number Names

During unreflected everyday life, using number words as proper names, e.g., while head counting attendant children,

Figure 10 Important difference in the usage of proper names versus number names.

easily happens. However, numeral words are not proper names. Let us consider the head counting of five children in comparison to calling them by name (Figure 10). What happens, when Tom leaves the row?

The assignment of names does not change, but the assignment of numeral words does with all children following Tom. In this respect, only the assignment of words marked in yellow is appropriate. In order to learn the content of number words, environments of events are much more needed than environments of denomination.

Object View–Process View

In case of object view, counting refers to objects, e.g., plates on a table; whereas in case of process view, to incidents, e.g., sequences of action conducted by someone involved. (Most commonly spread, counting applies to measuring the number of elements of a set of objects. When learning calculation, an understanding of counting as engaging in actions of greater importance. The first case refers to object view, the second to process view.)

When plates are to be placed on a table, they have to be taken from somewhere. In the object world there arises the problem of a subtraction happening in the cupboard from where the plates are taken and an addition happening on the table the plates are put onto. In the process world it is a person's potential to carry out an action. Therefore an environment is needed in which this action can take place. It is true that the order of elements is not important during counting. This finding of invariance of order became known as one of the five counting principles by Gelman and Gallistel (1978). However, it may not be overlooked that this counting principle is not a basic principle useful for comprehending calculation. Every number has its fixed position in the number space. Hence, four always comes after three. With the help of the process view the number space can be mentally captured by means of an acting person in his specific environment.

Focusing on actions and changes as opposed to objects is challenging. Consequently it is beneficial to promote children's functional-logical view.

Let us have a look at the situation of playing a game of dice (e.g., ludo) with children. First, it is necessary to discuss with the children that the quantity of the diced dots states how many times one may jump forward with the counter. The goal is to count the jumps and not the pads that lend themselves to counting as well. This settles the question as to where the focus during the counting process should be: on the action executed by the counter.

This process shows, if children are unable to understand counting as counting forward by one, starting with zero, their approach to calculating is hindered. Furthermore, if no attention is paid to finding situations in which children experience counting forwards as well as counting backwards, their approach to subtraction is hindered in comparison to addition.

Building and Strengthening a Culture of Reasoning

For many years we have been running an academic meeting point for early enhancement in mathematics education called 'mathemagic.' The meeting point's goal is a holistic support and enhancement of early mathematics education, respectively. Particular emphasis is placed on children needing support or especially talented children and facilitating each child's individual cognitive approach to mathematics.

Figure 11 A three is rolled. This means, the counter may jump forward three times – thereby visiting all four pads.

Figure 12 Initially, the counter is on the first pad. So far, it did not jump yet, i.e., zero times.

Figure 13 The counter jumps from the first to the second pad. It jumped once.

Figure 14 The counter jumps one more time. In total it has now jumped twice. It jumped from the second to the third pad. If pads were counted, one could stop now – matching the three dots on the die. This is a typical mistake when focusing on an object view instead of a process view.

Capacities of Mathematically Talented Children

One important undertaking of the meeting post was hosting an annual Mathematics Olympiad in which 2000 third graders from approximately 90 primary schools have taken part during the last 13 years. The Olympic tasks were designed to challenge children to give reasons for their solutions. Children's responses to the example 'Tiffany's tricky number task' (Figure 16) vary from no answer, a single numeral example without any reason (e.g., 'If $4 - 2 = 2$, then the task

Figure 15 The counter jumps one more time. In total, it has now jumped thrice. This time, it jumped from the third to the fourth pad. By performing three jumps according to the diced dots, the move is finished.

fits.'), stating several possible numeral examples without special result relation (e.g., '4 and 2, 6 and 4, 3 and 1, 2 and 0, etc.') or with stronger relation to the construction of the result (e.g., 'Tiffany could: $3 - 1 = 2$, $4 - 2 = 2$ and doing until ∞ – nearly $\infty = 2$. Tiffany could not: $3 - 2 = 2$ or $5 - 100 = 2$ and $5 + 0 = 2$.') to complete conceptual linguistic examples (e.g., 'All, as long as one of them is two numbers higher' or even 'The numbers always have to be apart as much as the result is.'). Only in the last case the relational nature of the numbers is successfully described in a way that allows capturing all (!) possible number pairs that satisfy Tiffany's first equation.

Figure 16 Task example from the Meeting Point's Mathematics Olympiad for third graders.

This displays the profound argumentation skills achievable by mathematically talented children. However, there still is a demand for initiation, nurture, and maintenance of an improved culture of reasoning, already with young children. In formal education, more importance has to be attached to not just reciting and testing number sentences, but on fathoming the connections of validity of these number sentences.

Mathematical Playworlds Boost Reasoning

The art in teaching an understanding of numbers lies in providing children with adequate arithmetic experiences based on counting. Psychological studies indicate that already infants can differ between one, two, or three objects, but are unable to differ between approximately four to six objects. Also, infants notice when one object is added to another or when one of two objects is taken away (e.g., Geary, 2007).

Therefore the first interesting number in terms of counting onwards is four. Numbers are systematic; so children should become acquainted with numbers in a systematic environment.

Event-Related Number Space Orientation

In the ENSO (event-related number space orientation) playworld (Figure 17), it is possible to explore the number range from zero to nine. This suits the later to be learned numeral diction of the decimal system. Cover sheets are used to focus on playing in a certain area, e.g., in the beginning just the number range from zero to four.

The ENSO playworld is inhabited by Hoppies and their animal companions who all travel by jumping. The number space is created by means of 10 places with ropes serving the purpose of holding balls. There are no balls at the starting space; no jump has been carried out yet. From this point onwards, there is always one more jump (basis for addition) or one jump back (basis for subtraction) possible. The balls on which a counter is standing can be counted, but also – and more importantly – the number of jumps necessary to reach a certain destination. Alongside the ropes runs a wooden plate serving as a path where jumps are also possible.

One Hoppy could e.g., start with zero balls and do three jumps. Simultaneously, an animal companion could do three jumps as well, also starting with zero, but on the path. If all goes

Figure 17 Mathematical playworld 'ENSO' (event-related number space orientation).

Figure 18 Number line from 0 to 3.

Figure 19 Logic game 'TooFP' (three out of four panels). (Example: x+3=4; 'Where from' (c) is unknown).

well Hoppy and his friend can wave at each other because their destinations fit together. This procedure can lead to an understanding of the number line. Also questions such as why it makes sense to count 'just' three when there are four lines can be discussed (Figure 18). One clever thing about the ENSO world is that the path itself does not contain lines that could be seen as countable objects and thereby hindering the process view.

Number Range Extension 'Zero–Four'

When jumping moves in the number range from zero to three are flexibly conducted – forward and backward, starting at different places – an extension suggests itself. The jumping game is enlarged by executing three jumps from the start and then one more jump. This process is analogical to the familiar situation of executing one more jump after having done two jumps. At first, a word is missing: The word for expressing how many jumps are necessary to reach the new destination from the starting point. The new word associated with this series of events is 'four.'

Components of Calculations are Connected

Various game actions are possible within the ENSO world. A game involving several number relations at once is the logic game 'TooFP': Three out of Four Panels.

The basic idea is: 'Define three of four panels. Draw conclusions' (Figure 19).

By means of the upper four display panels (Figure 19), movements of the counters in the ENSO playworld can be described or prompted. Sliding plates (displayed in the upper drawings through the green shaded areas) allow settling agreements. The lower four arrays verbalize the reading of the panels.

In the given example (Figure 19) the task is: $x + 3 = 4$ as shown by the area marked in white and the green shaded area, respectively.

The 'direction' of movement as shown by the panels has been set: 'count up' (a). Also, it has been set 'how often' the move should be performed: 'three times' (b). The starting point ('where from' (c)) is unknown and has to be found out.

Lastly, the final position is defined ('where to'(d)). In the example, it is 'four.'

By dint of this information it can be reasoned where the counter came from. The definitions also allow exploring possibilities and impossibilities. This kind of reasoning boosts the logical intellectual power. One advantage of mathematical playworlds lies in the possibility to discuss mathematical situations long before the script needed in formal calculation has been learned. At first, children are able to do a lot more mathematical thinking than they could do mathematical writing. This potential should be used for the children's benefit.

Spiral Stairs of Calculation

A further investigation of the decimal system can be achieved with the help of the mathematical playworld called spiral stairs of calculation (SSC), where the counters can move within the number space from 0 to 19 (Figure 20).

Due to the circularly arranged poles with balls, in the inner circle from 0 to 9, in the outer circle from 0 to 19, strategic counting operations can be considered. A counter on the inner circle could e.g., start on three balls and do two jumps upwards to reach five balls. Now it can contact its animal friend on the outer circle that starts on 13 balls and also jumps upwards twice and tell him on which number of balls his

Figure 20 Mathematical playworld 'SSC' (spiral stairs of calculation).

move will end, on 15. By means of the calculation $3 + 2 = 5$ and the underlying decimal construction the result of the calculation $13 + 2 = 15$ can easily be deduced. Structural features of the decimal system are elucidated by the color of the balls. The balls in the inner circle are orange, just as the balls from 0 to 9 on the outer circle. The following 10 balls on the outer circle are green though. Further 'easy' calculations where the result can 'easily' be deduced can be looked for and found. Examples could be games for the situations $4 + 10$ (just jump at the corresponding place on the outer circle) or 13 – 3 (just jump on the outer pole with no orange balls) and many more.

The inner circle of the SSC can already be used with preschoolers. In the following section we are going to demonstrate two characteristic discussions from the context of our play lessons.

Calculations Are Connected

In the present situation, several poles have already been completely equipped (Figure 21). In the up to now last step it has been found out that four more balls would fit nicely to the five balls that already have been placed on the nine-ball pole ($5 + 4 = 9$). Now five balls are handed out for the eight-ball pole, the task being to consider, how many further balls can be added.

A 5-year-old preschooler explains in this playworld where no formal notation is used that the answer to '$5 + 3 = 8$' must be 'three.' The reason being: during the beforehand discussion of the task '$5 + 4 = 9$' it had turned out that the missing number of balls is 'four.' As an introduction to its statement the preschooler points out 'I knew that!' after the correct answer 'three' had already been given by another child at the playing table. His inference is simple: For nine balls only one more ball and so with eight balls only three balls have to be added. Without having the eight balls before his eyes the child has an overview in the mathematical playworld that '$9 = 5 + 4$,' '$9 = 8 + 1$,' therefore '$8 = 5 + 3$.'

Figure 21 Filling the spiral stairs of calculation using certain stages.

Does It Make Sense to Think of Zero as an Even Number?

Zero deserves special attention because its understanding is fundamental for the use of the decimal place-value system. One counts from 0 to 9 per place and then starts all over again. In the SSC there is a fixed space for zero balls: the place where the space for balls is one ball smaller than the space for balls at 1 ball, just like the space for balls at 1 ball is smaller than the space at 2 balls. In this way the use of zero can be implemented in the arrangement of thoughts. While walking the SSC downwards, connumerating the place can easily be denominated, as well as it should be denominated when walking upwards. And of course, a counter standing on the starting place, has not jumped yet, i.e., it jumped zero times.

In a game situation with preschoolers the discussion arose as to where in the SSC it would be possible to place a foam-rubber slate so that the number of balls under and over the slate is equal (the guiding question being 'Where else is this possible?'). Firstly, the poles with 1–9 balls were successfully investigated (Figure 22), afterward the space for zero balls was given consideration.

Figure 22 Exploring some properties of numbers using blue foam rubbers.

Group A:		
Teacher:	I tell you there is another place…	
John:	Yes, I know one…	
Teacher:	Which one, John?	
John:	The zero, *because* zero is at the bottom…and at the top.	[Laughs.] [Gestures at the starting place and for the lower zero balls.] [Gestures at the starting place for the upper zero balls.]

Group B:		
Teacher:	I tell you, that…	
Rita:	Ah!	[Raises her hand.]
Teacher:	…it works *again*.	
Rita:	I know it…	
Nora:	The zero, *because* then everyone gets nothing.	[Nora gets a foam-rubber slate from the teacher.]
Teacher:	Rita, what was it, you wanted to say?	
Rita:	Zero.	
Teacher:	Why?	
Rita:	*Because*, uhm, then there is nothing on either side.	

Similar to Rita's argumentation is Tina's from Group C, but she makes a remarkable addition:

Tina:	Uhm…*because*, *because*, *because* with zero, there, there, there is nothing on each side. *So* it is equal.

The apodosis 'So it is equal' nicely shows that Tina can work with 'nothing' as a number.

Mathematical ideas are grounded on reason and argument. By means of mathematical playworlds, children are introduced to applying a connected series of statements to establish mathematical meaning. Thereby they get a better understanding of the realm of numbers.

Concerning early childhood mathematics, the question is how children can learn the usage of and the necessity for words to articulate reasons and in which kind of situations this may be learned. Internationally there still is not very much knowledge about these questions, so research is dearly needed.

Place-Value System: Mathematical Playworlds as a Mediating Tool for Understanding Ideas Embedded in Mathematical Symbolism

Understanding the functioning of the place-value system that builds the foundation for the common notation of numbers and the algorithms for the basic calculation operations learned at primary school is a cognitive challenge. In our days, this notational system is used almost worldwide to operate with natural numbers – on paper, using electronic calculation devices or last but not least the computers. Children of cultures like China or Japan seem to have some advantages in getting familiar with this mathematical concept because their native language fits better than others to the logical construction of this rule-based symbolic notion (e.g., Miller et al., 2005). In Western countries, major problems of kids' usage of the place-value system in calculation tasks are discussed (e.g., Ashlock, 2010; Fuson et al., 1997; Haylock and Cockburn, 2013; Kamii, 1999). Children e.g., do have difficulties to connect the written symbols with objects (Figure 23 left) or to use calculation methods such as the addition algorithm (Figure 23 right).

Figure 23 Example of possible difficulties when learning the decimal place-value system.

Usually people suggest improving children's thinking in structures of 10 to understand the place-value system and therefore using material similar to base-ten blocks or ten-sticks and dots to help children. For this purpose, the instructions for multidigit addition and multidigit subtraction in vertical layout are strongly based on carrying and borrowing together with the principles of exchange and decomposition. Little 1s come in, e.g., in case of exchanging 10 tens to 1 hundred, then a little 1 is to be written at an appropriate place in the hundreds column. From a mathematical viewpoint the usage of material like base-ten blocks has to be put into question. Little 1s do not make sense. 1 hundred, of course is much greater than 1 ten or 1 unit. It has to be noted that the decimal system solely allows the digits from 0 to 9 at each place. Exchange and borrowing are not provided for in terms of the notation. The decimal system is a counting device in which counting forward and backward is noted in a special way (e.g., Schwank, 2013). Its functionality is displayed in the following mathematical playworlds.

Stellanian Accounting System for Their Balance of Starthaler

The first Stellanians are Hella, Tella, and Ulla (Figure 24).

They are responsible for the Stellanian accounting system using special rung ladders for recording Starthaler (Figure 25).

There are rules for how to use this particular accounting system

1. Each of the three Stellanians has its own ladder. None of them may leave their ladder during a recording process.
   a. Jump from rung to rung with the Stellanians. How often can each of them jump from the bottom to the top? And back again?

Figure 24 The Stellanians Ulla, Tella, and Hella.

Figure 25 Ulla, Tella, and Hella positioned at their rung ladders.

2. If Ulla jumps one rung upward this means the balance increases by one Starthaler. If Ulla jumps one rung downward, the balance decreases by one Starthaler.
   a. What balance can Ulla display?
   b. Which changes can Ulla record?

Figure 26 How can Ulla and Tella cooperate to solve the task 9+1?

3. Tella's case is similar to Ulla's. But when she jumps from rung to rung, the balance increases or decreases by 10 Starthaler.
   a. What balance can Tella display?
   b. Which changes can Tella record?
4. In Hella's case the jumps are worth 100 Starthaler!
   a. What balance can Hella display?
   b. Which changes can Hella record?
5. The three of them can work together!
   a. What balance can they display together?
   b. For recording changes together they have to think and cooperate carefully.
      – Find cases of change in the amount of Starthalers that they may record together easily.
      – If the amount of 23 Starthaler is increasing by 14 Starthaler the recording is rather simple, right? But if the amount of 9 Starthaler is increasing by 1 Starthaler, there is a problem, is not it? (Figure 26)
      – If the amount of 578 Starthaler is decreasing by 467 Starthaler, this is a great loss of Starthaler, but the recording is easily done. Why? But if the amount or 10 Starthaler is decreasing by 1 Starthaler, the loss of Starthaler is only little, but the recording turns out to be challenging. Why?

The rung ladders provide an overall system for displaying all numbers from 0 to 999 (Figure 27: left). The transition to decimal script is achieved by labeling the individual rungs,

Figure 27 Possible numbers that Ulla, Tella and Hella can display (from 000 to 999).

e.g., the lowermost rungs are labeled 0. This is the Stellanian's starting position where no jump has been carried out yet. All further rungs on a ladder are labeled according to the number sequence, ending with 9 as label for the last rung. From the lowermost to the uppermost rung nine jumps are necessary.

The combinations in which Hella, Tella, and Ulla can take a seat on a rung add up to 1000 possibilities (Figure 27: right). The blue lines display that Tella has 10 options to choose a rung for herself according to every rung that Ulla has taken a seat on. This means, they have on the whole 100 possibilities. Now Hella, for her part, can choose a rung for herself according to each of these 100 possibilities, resulting in a total of 1000 possibilities.

The comprehension of numbers is based on the thorough immersion in the functioning of the place-value system by mastering the mental arrangement of the Stellanians on their rung ladders (Figure 28).

In advanced lessons, using the lesson format of dialogic learning (Gallin, 2012), children can experiment with changing the number of rungs. They can convince themselves that the number of rungs is variable: It is possible to choose from two rungs to any higher number. The already known principles of the decimal representation of numbers as well as the principles of decimal calculations function analogously.

Conclusion

Obviously, teaching preschoolers to know that the quality of being an even number can be attributed to zero is not the point. Nor is it that people should know the number to express the length of the diagonal in the introductory example up to 10 or more decimal places.

Nonetheless, we have advisedly chosen these examples. The goal was presenting something mathematical that adults familiar with everyday mathematical situations do not simply take for granted. Hence, there is a need for educated inferential argumentation. Concerning mathematical learning processes, thinking theoretically through

Figure 28 Possible plus and minus actions of the three Stellanians.

a problem by means of logical reasoning is essential. Children need occasions to get familiar with mathematical concepts in a reflective way in order to develop their mathematical thinking.

We are convinced that – just as children are obviously able to learn any language as their mother tongue – children can, in principle, also learn the universally valid ways of expressing elementary mathematics. From the viewpoint of cognition, this learning opportunity is initially independent of cultural affinities. The question is to what extent children are conceded to educational opportunities and to what extent these are professional.

This kind of professionalization certainly asks for further research. For the future it would be eligible to run an increased amount of national as well as cross-cultural studies that help exploring ways in which young children can acquire the ability of mathematical reasoning and thereby develop mathematical concepts. For that matter the focus should be not so much on learning and thinking results but in learning and thinking processes. Moreover, further methods and procedures to positively influence mathematical reasoning are to be developed. One promising starting point might be providing learning environments rich in mathematical content such as mathematical playworlds.

Mathematical Models in Geography

Abstract

This article explores the role of mathematical modeling within human geography. The focus is thematic in nature providing an overview of a highly diverse literature. The approaches to modeling in geography are organized as a typology that classifies models according to genre and applications. Key methodological challenges that distinguish geographic modeling from that practiced in other social science disciplines are discussed. These include issues related to spatial dependence, changes in geographical scale as well as the question of local contextual effects, and their treatment in geographical models. This article ends with some comments about the future prospects for geographical modeling.

Introduction

This article explores the use of mathematical modeling in the field of human geography. The focus is on providing an overview of the definition of modeling in human geography, main research directions, methodological and theoretical issues, and a view of the future prospects of modeling. By necessity, the focus is broad rather than in-depth, and thematic rather than technical.

The article is organized as follows. Definitions of the term model are first briefly reviewed to provide context; next a typology of models in geography describes different types of models and their main uses. Attention is then directed to a number of important challenges in geographic modeling. The article ends with a view of the future for modeling in human geography.

Definitions

The term model has taken on multiple definitions within the field of human geography. Moreover, as the discipline has experienced paradigmatic shifts, the status, roles, and definitions of models have also evolved and varied. As in many social sciences, theories and models within geography are closely connected. Indeed, many social science theories could be described as models as they are often composed of a set of interrelated hypotheses rather than empirically validated laws (Cadwallader, 1985).

A common view of a model within geography is a simplified representation of some aspect of reality. The representation abstracts the central components of interest to allow for an investigation of their role in the process under study, while the aspects less central to the process are omitted from the model. This representation can be articulated in one of the three geographic model forms: (1) iconic, where representation is based on a reduction in scale, such as a classroom globe; (2) analogue, relying on both changes in scale and transformation of the properties of the system, as in a map; and (3) mathematical, in which formal symbols and equations are used to represent the system. The focus here is on this last form of geographical model.

As knowledge is developed through an ongoing interaction between theory and observation, mathematical models play a critical role in this process, serving as an empirical counterpart of a theory which is compared against reality. This conventional view of a geographic model might be characterized as the 'model of a process' perspective. There is a second, somewhat more subtle but equally important, view of the term model in geography, and this is the 'model as a process' perspective. Models are not simply about the world but are also about our knowledge about the world (Haines-Young, 1989). In this way, the process of modeling can be seen to serve three useful purposes. (1) It forces the researcher to be explicit concerning theoretical constructs, hypotheses, and other aspects of their understanding of a system. (2) Formalization of a problem in an empirical model can be of great utility in revealing complex indirect effects that are not articulated by the theory. (3) Models can assist in policy analysis where there is often a gap between existing substantive theory and the real world that policy makers are confronted with.

A Typology of Geographic Models

Given the integrative nature of geography as a social science, a wide variety of models currently exist within the discipline. Human geographers have employed a vast array of models based on different mathematical frameworks to study processes at widely ranging spatial scales for a variety of purposes. Consequently, a cataloging of these models is clearly beyond the scope of this article. Instead a generalized structure is presented in which human geographic models can be categorized according to three dimensions: (1) spatial scale, (2) mathematical framework, and (3) applications.

Spatial Scale

One important dimension of spatial analysis in human geography concerns the spatial scale of the study. Human geographers have developed mathematical models for scales ranging from the spatial decision-making of individuals, to the spatial structure of housing values across neighborhoods in a city, to patterns of uneven development of regions

within a national setting, and to studies of international trade flows.

Microscale

Microscale geographical models are those that represent a spatial system at its elemental or individualistic level. *Agent-based models* (ABMs) represent the behaviors and interactions of individual actors located in space. Different types of agents are included in these models depending on the context. For example, in an ABM exploring residential search processes in an urban setting, the agents might be households stratified by household size and income, who make decisions based on preassigned rules that may reflect underlying microeconomic principles (Ettema, 2011). Through an agent's interactions with other agents in bidding for housing units, complex patterns of market outcomes can emerge.

Closely related to ABMs are *cellular automata* (*CA*) *models* (Clarke et al., 2007). CA models are similar in spirit to ABMs since they are individualistic in their representation; however, the individual units are typically taken to be cells or discrete spatial zones in a CA model rather than human individuals. The focus is typically on how the cells transition between land uses, such as developed or undeveloped, over time given simple rules, for example:

$$S^l_{i,t+1} = \begin{cases} 1 & \text{if} \quad \sum\limits_{j \in \omega_i} S^l_{j,t} \geq \alpha_l \\ 0 & \text{otherwise} \end{cases}$$

where $S^l_{i,t+1}$ is an indicator variable specifying that the land use class for cell i at time period $t + 1$ is set to l if a sufficient number (α_l) of its neighbors (the set ω_i) were in class l in the previous period.

Mesoscale

ABM and CA models can be viewed as the latest in the evolution of models designed to study the human spatial structure of cities. Earlier models were more aggregate in their representation of cities reflecting their reliance on early urban economic and land use theory where representative consumers maximized their utility in deciding where to consume housing subject to a budget constraint (Alonso, 1964). These models were predicated on an assumed central business district (CBD), serving as the point of maximum access for the surrounding urban area, and increasing transportation costs with movement away from the CBD.

While the origins of this monocentric model are found in urban economics, geographers have played an important role in developing extensions of this classic framework to the case multi- or polycentric city models (Odland, 1978). In these models, the city may have several nodes of concentrated economic activity, and the articulation of the role of accessibility in determining land use patterns in such a context results in a highly varied landscape. More recently, geographers have continued the discretization of cities by adopting novel fractal geometric approaches to study urban form and structure (Batty and Longley, 1994).

Macroscale

Closely related to the work on internal urban spatial structure have been efforts to develop models of urban systems and their evolution. An urban system consists of the complete set of urban areas and cities within either a region or nation. A central concern in this literature has been the size distribution of cities within a system (Carroll, 1982). These models consider the population sizes and rankings of a system's cities through the use of the so-called rank–size curves, which take the following general form:

$$\ln(r_i) = \alpha + \beta \ln(p_i)$$

where $\ln(r_i)$ is the natural logarithm of the rank of city i with respect to size and p_i is the city i's population. A large number of empirical studies have found that a value for β close to 1 well describes many developed national city-size distributions. As Fujita et al. (1999) have noted, part of the fascination with the rank–size rule is that it comes as close to an empirical law as any relationship in the social sciences.

The work on city-size distributions has been paralleled by an extensive body of modeling on regional development, growth, and inequality dynamics, where the focus is on variation in standards of living across regions and over time. One branch of this literature has adopted modeling frameworks from international growth theory to the case of convergence between regions within a single country (Rey and Le Gallo, 2009).

Other regional models focus on the economic structure and performance of urban and regional units. Economic base models posit that a city or regional economy can be divided into two components. The first component consists of those activities that produce for markets outside the region, which are thus classified as the 'export base.' The second component, referred to as the local sector, consists of activities that produce for internal markets and provide goods and services for local residents and businesses. The central idea in these models is that local service employment is derived from the expansion of the export sector, which is the basis for economic growth in the region. An extensive literature has evolved around the issues of implementing and applying economic base analysis (Krikelas, 1992).

Regional input–output models can be viewed as an expansion of the economic base construct to consider a more detailed set of interindustry linkages within the urban or regional economy (Dewhurst et al., 1991). Like economic base models, the earliest regional input–output models focused on a single regional economy; however, input–output modelers have also extended these frameworks to examine the nature of interregional interindustry interactions. These efforts have provided rich insights into the nature of modern space economies.

Spatial Scale Issues

A long-standing issue in spatial modeling is the so-called modifiable areal unit problem that arises when inferences about the nature of a phenomenon change with the spatial scale used to study the phenomenon. This has been illustrated in studies of the correlates of voting behavior in which the relationship between age and propensity to vote for a particular party has been demonstrated to vary both in strength and direction as the analysis moved from the individual level, to census block, county, and state.

A related challenge facing geographic modelers surrounds the relationships between processes that operate at different scales. For example, there is a growing need to integrate mesolevel models of urban land use with macromodels of a regional economy so that the interaction between dwindling land supply and aggregate regional economic growth can be analyzed and better understood. On a broader level, there is also a pressing need to analyze the relationships between regionally focused human-induced modification of the physical environment and global climate change.

Mathematical Framework

The second way one can categorize and group different types of models within human geography is to focus on their underlying mathematical framework. Here distinctions can be made based on three dimensions: (1) stochastic or deterministic model, (2) spatial interactions between units taken into account, and (3) framework integrated in that it treats multiple subsystems or is it focused on a single process/system.

Deterministic versus Stochastic Models

A deterministic model is one in which the values for the dependent variables of the system are completely determined by the parameters of the model. In contrast, stochastic, or probabilistic, models introduce randomness in such a way that the outcomes of the model can be viewed as probability distributions rather than unique values.

Deterministic models have the advantage of often being amenable to mathematical analysis, as in the case of using ordinary differential equations to model the geographic spread of infectious disease within human populations. Simulation of these models through parameter and input adjustment can provide important insights into the quantitative and qualitative features of epidemics (Sattenspiel, 2009).

The mathematical clarity offered by deterministic models can, however, come at a cost of decreased realism. Because of this, most of the mathematical modeling done in human geography is stochastic. These models provide a framework to represent spatial uncertainty in mathematical modeling that is well recognized as an important issue in its own right (Goodchild and Zhang, 2002). That uncertainty can surround a number of dimensions of the modeling effort including data uncertainty and model specification uncertainty, parameter uncertainty, among others. Stochastic models can also provide estimates of confidence intervals around point estimates and forecasts.

Global or Local, Multi- or Interspatial

A central concern in human geographic modeling is the interaction across space between the observation units. This reflects Tobler's *First Law of Geography* that "everything is related to everything else, but near things are more related than distant things." The process of spatial interaction is therefore a key mechanism for creating the spatial structures underlying human societies. At the same time, spatial interaction can also be influenced by the underlying spatial structure of the society. Spatial interaction models are used to study a broad spectrum of human spatial behavior that takes the form of movement or communication over space (Fotheringham and O'Kelly, 1989). Some of the most common types of spatial interaction, which have been modeled, include migration patterns, commuting, commodity flows, and retail shopping behavior.

Spatial interaction models illustrate how different locations can become functionally interdependent. This can be seen by considering a simple interaction model:

$$T_{i,j} = \frac{P_i P_j}{d_{i,j}^{\beta}}$$

where $T_{i,j}$, the degree of spatial interaction (e.g., migration, trade flows, air travel) between places i and j is directly proportional to the sizes of the population at the original location P_i and the destination P_j, and inversely proportional to the distance between these locations $d_{i,j}$. The strength of the decline in interaction with increasing separation is captured by β, the distance decay coefficient.

In models such as these, the spatial interactions appear as dependent variables in that predictions between each pair of locations i and j are the outcomes of the model. Spatial interactions can also appear in human geographic models as explanatory variables as well. In the spatial econometrics literature (Anselin, 2000), an example is the spatial lag specification used in the regional convergence literature:

$$y_i = \rho \sum_j W_{i,j} y_j + X_i \beta + \varepsilon_i$$

where y_i is the growth rate for regional economy i, which is related to traditional determinants of growth X_i as well as the weighted average of growth rates in neighboring regions reflected in the term $\sum_j W_{i,j} y_j$. A final issue related to spatial interaction is the proper specification of contextual effects in developing models of socioeconomic systems. Geographers are faced with the twin challenges of building models that capture general systematic properties while also capturing the richness of spatially explicit variation in many social phenomena. At first glance, these two challenges appear to be mutually exclusive as the search for empirical regularities would seem to rule out local variations and nuances. However, an active branch of geographical modeling has focused on the so-called 'local spatial analysis' in which methods are being designed to identify 'hot spots' and deviations from overall general patterns. This opens the possibility of integrating both local and global types of modeling.

Integrated versus Isolated

The final genre in this classification is found in integrated human geographic models. A model can be classified as integrated in a number of ways. *Substantively* integrated models encompass a number of different activities within the same analytical framework, recognizing the interdependencies between, for example, regional labor markets, housing markets, demographic processes, transportation networks, and environmental systems (Briassoulis, 1986).

Spatially integrated models provide a comprehensive treatment of one or more geographical dimensions of a process. For example, in multiregional economic models, the interactions between different regional economies are treated as endogenous to the system. A second important class of spatially integrated models are those that focus on the relationships

between different levels within a spatial hierarchy, such as global, national, regional, and urban (Jin and Wilson, 1993).

The final type, *methodologically* integrated models combine different modules, each with a potentially different mathematical structure within the larger comprehensive framework, so as to achieve modularity and flexibility (Rey, 2000). All types of integrated models are enjoying increasing popularity with the increased interest in interdisciplinary problem solving.

Applications of Models in Human Geography

Broadly, human geography models are used for (1) statistical investigation, (2) optimization, or (3) simulation and forecasting.

Statistical investigation is perhaps the most common, often used method for hypothesis testing. For example, human geographers have used specialized regression models to investigate issues such as urban decentralization, regional income inequality, historical voting patterns, and socioeconomic aspects of deforestation. What distinguishes these types of investigations from those in other social sciences is that the spatial dimensions assume a central focus.

Two broad classes of statistical modeling in geography are recognized. The first is exploratory, where the focus is on the identification of spatial pattern, testing for spatial clustering, and departures from random sampling. Models and methods for exploratory spatial data analysis have attracted a great deal of attention (Getis, 1999).

The second approach to statistical modeling is known as confirmatory spatial data analysis. Here the field of spatial econometrics has played a central role in developing new methods to deal with the treatment of spatial autocorrelation and spatial structure in regression models (Anselin, 2000). Spatial autocorrelation presents a fundamental problem to the application of traditional (i.e., a-spatial) regression methods, given that their application for inferential purposes is based on an assumption of random sampling, which is rendered invalid in the presence of spatial autocorrelation.

Optimization models are used for normative purposes to identify the optimal solution for a given problem. All optimization models have a quantity that is to be maximized (or minimized) as reflected in an objective function, for example, in the case of the well-known transportation model:

$$\text{Minimize } L = \sum_{i=1}^{n} \sum_{j=1}^{n} T_{i,j} Q_{i,j}$$

subject to:

$$D_j \leq \sum_{i}^{n} Q_{i,j} \forall j$$

$$S_i \geq \sum_{j}^{n} Q_{i,j} \forall i$$

$$T_{i,j} Q_{i,j} \geq 0 \forall i, j$$

where the objective is to minimize total transportation costs. The costs are a function of the unit transport cost, $T_{i,j}$ and the number of units shipped between location i and j, $Q_{i,j}$. The solution has to respect a number of constraints such that, the amount shipped to each region satisfies demand in that region D_j, the amount shipped from a region is no greater than the supply in the region S_i, and all costs are nonnegative.

Several types of optimization models have been developed within human geography. *Location-allocation models* (Gosh and Rushton, 1987) typically involve a set of consumers distributed over a given area and a second set of facilities (stores, public services) to serve them. These models are used to allocate the facilities to best serve the customers. Optimization methods developed by geographers have also been used to delineate regions for specific objectives, such as school and political zone redistricting.

Simulation and forecasting models are used to study and compare the responses of a system to policy or environmental changes. Examples of these applications can be found in the areas of integrated environmental human analysis (Knight, 2000) and the analysis of trade policy impacts on regional economies (Warf and Randall, 1994).

Prospects and Challenges

Prospects

Recent developments, within and outside human geography, bode well for the future development of modeling. Within the discipline, modeling is now well established as an important area of research, and its role in legitimizing human geography as a discipline is widely accepted.

Among the social sciences, the importance of space has grown in recognition. The rediscovery of the geographical dimensions of many social problems has given rise to some new research agendas within these disciplines. Scholars in other disciplines are turning to geography and geographers as they address this new terrain. Coupled with the demand for interdisciplinary approaches, the opportunities for geographic modeling to contribute to more sophisticated analysis in social science research are bound to increase. Human geographers active in the development and application of geographic modeling will have an important role to play in strengthening human geography's claim as an integrating discipline within the social sciences.

Challenges

In order for geography to fully realize this claim, two challenges will have to be addressed:

- space–time modeling; and
- computational complexity

Space–Time Modeling

As geographic modeling becomes more widely used in other social sciences, the need to consider temporal as well as spatial dimensions of processes will grow. As argued by Cressie (1993: p. 24), a purely spatial model typically has no causative component but rather reflects the aggregation of short-term effects over a fixed time period for which data are available. Static, or purely cross-sectional, models are those in which time is not explicitly incorporated in the sense that no time subscript

formally appears in the model, only spatial coordinates are used to index the observations. Implicitly, of course, the models are solved for the moment in time in which data used to calibrate the model were obtained. This is the case for models in which cross-sectional observations are obtained for different geographic locations. Underlying such models is the assumption that the system under study has reached some sort of equilibrium, which is a necessary condition to enable parameter estimation.

In dynamic models, time is given an explicit representation. Values for the dependent and explanatory variables are now indexed by spatial as well as temporal coordinates. Different forms of dynamic representation arise from alternative ways of linking observations across space and time. In a comparative statics approach, different inputs are specified for a model at each time step, leading to different equilibria, and a comparison of these different solutions can reveal insights about how the system adapts to changes in inputs.

The second class of dynamic models in human geography adopts a disequilibrium perspective in which the focus is on how shocks to the system result in movements away from equilibria and the time path involved in the evolution of the system. In most human geographic models, time is specified as discrete, using data observed at regular fixed time intervals (e.g., annual, daily, etc.); however, in some instances, continuous time modeling has been adopted to study human travel behavior (Brockmann et al., 2006).

At present, there is a rich and mature body of methods for dealing with time series, and a modest but growing set of methods for spatial series. Methods for dealing with both dimensions simultaneously within the same model face significant challenges due to the disparity in different types of space–time data and the associated substantive problems that can be considered (Goodchild, 2013). A prominent type of space–time data is tracking data, in which a series of point observations in space is recorded at different time intervals to study human movement, for example. A second form of space–time data compares time sequences of remote sensing data to detect land-use change. Still other forms of space–time data underlie the CA and ABMs described earlier, and polygon coverage data consisting of longitudinal observations on areal units such as census tracts over multiple time steps. Distinct differences among these data types have hindered the development of a unified approach to space–time modeling in human geography.

Computational Complexity

Technological changes have shaped some of the methodological issues that modelers face. In the past, discussions concerning data availability focused on the dearth of good data sets to base models on. Today, advances in data collection technologies (i.e., remote sensing, geographic information system, global positioning systems) have shifted the discussion to problems of too much data. Traditional geographic modeling techniques are ill-suited for these enormous data sets and novel new approaches will be required.

These new approaches will reflect the growing importance of the so-called *fourth paradigm of science* (Tolle et al., 2011) in which the use of models in human geography will shift from their traditional roles in theory development and testing, to other more exploratory purposes. Here, the application of exploratory spatial data analysis and data mining to data streams is used to uncover new empirical patterns that may lead to the new types of questions, and ultimately hypothesis generation and theory building. The distinguishing characteristic here is that the science and modeling effort is data instigated rather than driven by a priori theoretical constructs.

Coupled with the data avalanche induced by new geospatial technologies has been the rise of *geocomputation* as an approach within human geography involving the application of high-performance computing technologies to analyze digital representations of human activity in a geospatial frame of reference (Miller, 2008). Together with advances in cyber-infrastructure for geospatial analysis (Wang, 2010), human geographers can now develop models that incorporate parallelism, adaptive systems, and emergence that were simply not possible in earlier generations of computational infrastructure, but that now may provide more realistic representations of human geographic systems.

Finally, while the new geospatial technologies have fueled a resurgence of interest in geographical modeling and analysis, these technologies have also redefined the types of questions researchers are addressing. A promising development in this regard has been the rise of open-source software or shared software development among a research community (Rey, 2009). Prominent examples of open-source projects supporting spatial modeling in human geography are the Python Spatial Analysis Library (Rey and Anselin, 2010) and the R project (Bivand and Neteler, 2000). Beyond facilitating the dissemination of advances in spatial modeling and analysis methods through free software, open source has also had major impacts on pedagogy in training human geographic modelers.

Mathematical Models in Philosophy of Science

Zoltan Domotor, University of Pennsylvania, Philadelphia, PA, USA

Abstract

This article presents an overview of the most important foundational aspects of mathematical models used in science. The importance of mathematical models is widely recognized for their essential role in the acquisition and organization of scientific knowledge, and their success in representing the structure, mechanism, and behavior of real-world systems is undeniable. However, what are these models, in virtue of what do they represent, what is the basis for choosing one particular model over another, and how are models validated? These are some of the conundrums contemporary philosophy of science tries to solve. Answers to these and other problems are given in the general frameworks of *equationally* vs. *structurally* conceived mathematical models and their symmetry relationships. We illustrate several major types of models, their modifications and structural enrichments on a concrete extended example, known for its significant intuitive content.

On the most fundamental level, the basic questions contemporary philosophy of science asks and tries to answer about mathematical models used in science are as follows:

1. *What are mathematical models*? There are many issues buried in this question, known as the 'ontological puzzle': are models equations, formal systems, set-theoretic or category-theoretic structures, fictional entities, all of the above, or something else (e.g., 'mediators' between theory and the real world, autonomous tools of investigation, reconstructions of or formal stand-ins for so-called target systems)?
2. *In virtue of what do mathematical models represent the chosen aspects of a natural system, phenomenon, mechanism, or process under study – henceforth referred to as the target system – and how do model builders know whether or not a mathematical model correctly represents*? These are very hard semantic and epistemic questions, since the success of mathematical modeling in science is undeniable, but the nature of linkages between models and systems, underlying the models' success, is difficult to pin down. Einstein (1954, page 233) puts his finger on this central problem in his famous remark: "*As far as the propositions of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality*." Applied mathematicians, scientists, and systems engineers have always held the view that most propositions of an adequate mathematical model refer to reality in some way, because without such reference, the presence of mathematics in scientific representations would be unintelligible. A major problem is that a mathematical model-based 'representation' is generally not a variant of copying or mirroring.
3. *In what ways can mathematical models represent*? Mathematical methods form a huge part of scientific and engineering practice. A natural system under study may be represented by several different mathematical models, and conversely, a given mathematical model often represents many different (possibly unrelated) systems, both within and across various scientific disciplines. A large part of contemporary natural and social science is concerned with investigating the temporal and spatial changes in target systems. There are many ways in which models can and do represent such changes. To illustrate the *pluralism* in dynamical model types, recall the choices between deterministic and stochastic mathematical models, continuous-time and discrete-time models, process-based and agent-based models, classical and relativistic models, and so forth. Applications of mathematics in systematic studies of stereotype empirical systems tend to involve *parametrized families*, *hierarchies*, or *networks* of models.
4. *How are models validated, what is the basis for choosing one particular model over another, and when is a model acceptable*? Validation is an empirical procedure intended to determine the degree to which a mathematical model under consideration is an accurate representation of its target system within its domain of intended application. As products of model developers' cognitive work, mathematical models are not independent of human understanding. Nevertheless, their validity rests solely on their ability to predict experimental outcomes to within antecedently specified errors (irrespective of agreement with common sense and intuition) and on the degree of coherence with other accepted models.
5. *In virtue of what do mathematical models provide information about their target systems*? This question concerns the *epistemology* of models. We know that models usually represent their target systems in ways that uphold the basic principles of knowledge acquisition about them. However, according to the philosophers of several different realist persuasions, a mathematical model can serve as a reliable source of information about the target system only if it correctly represents the target system's structure, function, or behavior under consideration, that is, if researchers want to extract information from a mathematical model, they have to come to terms with how the model represents.

Having identified the basic questions about models studied by philosophers of science, we next summarize several corresponding answers. We gather them in one place largely to standardize the terminology. It should come as no surprise to the reader that there are several important questions to which philosophers of science do not have satisfactory answers.

Debates Over Mathematical Models in Philosophy of Science

Recently, philosophers of science have developed a large variety of approaches and solutions to the questions itemized earlier. We begin by reviewing some of them here and set the scene for a more detailed study of mathematical models, their construction, and application.

Mathematical Models

The question 'What are mathematical models?' has two prominent answers, which considerably simplify the inflationary use of the term 'model' in science:

1. In the first instance, there is the syntactic *equational* answer, advocated by logical empiricists in the 1920s and retained by most philosophers of science as the so-called *received view* or *standard conception* until the mid-1960s. The idea is to define mathematical models in terms of *systems* of (most commonly equational) *axioms* of some sort, modulo logical equivalence, stated in a (semi) formal language. According to the standard conception, equations together with chosen constraints and initial conditions are used in deriving numerous predictions that must then be compared with independently obtained evidential data, gained through measurement and experimentation. Repeated prediction–data comparisons form an integral part of model verification and confirmation. If the calculated predictions of a model under study and independently obtained data agree to within a reasonable error, then model users can be said to have a proper grounding for their growing degrees of confidence that the model correctly represents the target system. A model is *confirmed* when its observable predictions are borne out, and only highly confirmed models should be accepted by model users. From an empiricist perspective, a mathematical model is *empirically adequate* provided that *all* of its predictions are borne out. Unfortunately, a model user may never be in a position to *know* whether the model under study is empirically adequate. An inadequate model is usually reformulated by appropriately changing the assumptions under which it was constructed.

   The logical essence of real-world applications of models in the *empiricist received view* sense is succinctly caught in the following inference scheme:

$$\frac{\begin{array}{c}\text{Equations \& Init. Cond.}\\ (\text{Equations \& Init. Cond.}) \rightarrow \text{Prediction}\end{array}}{\therefore \text{Prediction}}$$

   Simply, empirically or contingently true equations combined with initial conditions together with mathematically sound calculations of predictions from these equations and initial conditions yield empirically true predictions that can be compared with experimental data. The model is viewed as inadequate if the agreement between prediction and independently obtained data lies outside of a reasonable estimate of error.

   The basic example of a model in the received view sense is the state equation $P \cdot V = R \cdot T$ of an ideal gas enclosed in a vessel. The real-valued macroscopic quantity P in the equation denotes gas pressure, quantity V stands for the vessel's volume, quantity T refers to the absolute temperature of gas in the vessel, and R is the gas constant, ensuring the equation's dimensional homogeneity. For another example of a model from the perspective of the standard conception consider the now well-known Lotka–Volterra differential equations $\frac{dx}{dt} = ax - xy$ and $\frac{dy}{dt} = xy - by$ of predator–prey interactions. A simple regression model in statistics is defined by a linear matrix equation of the form $Y = \mathbf{A}X + Z$, where Y is a (normally distributed) random variable, $\mathbf{A}$ denotes a coefficient matrix comprising constants, and Z stands for an independent error random variable with normal distribution. In theoretical physics, systems theory, and mathematical economics, the most common examples of mature mathematical models (in the received view sense) are special families of ordinary, partial differential, or stochastic differential equations, involving selected real-valued quantities and parameters, and usually derived from first principles and idealized target system specifications. In some cases, it is possible to solve these equations analytically, and in analytically intractable situations suitable discretization algorithms are necessary to obtain approximate computer-generated solutions.

2. There is an alternative *semantic* or *structuralist* answer to the question about the nature of mathematical models, first proposed by Suppes (1957, last Chapter) and Beth (1961), and further developed by those who followed them. The semantic view treats mathematical models as set-theoretic structures of some sort – typically sets with some kind of additional structure (e.g., relations and operations thereon).

   In the heydays of semantic model theory, Suppes (1988) and others argued that a scientific theory should be specified by the class of those set-theoretic structures in which the (equational) axioms of the theory are true. Accordingly, whenever the classical view specifies a model by a body of nonlogical axioms or other descriptive means, Suppes introduces a corresponding set-theoretical predicate whose extension coincides with the class of those set-theoretic models that satisfy the axioms. The choice of set theory as the best formal tool for representing theories is amply justified by its universal character. On this view, scientific models are nothing but appropriate classes of set-theoretic structures of the same similarity type. In fact, one can proceed a step further and consider *hierarchies* of models, starting from low-level *data* models and closing with high-level *theoretical* models. All this can be extended to networks of models in which the traditional notion of a scientific theory (i.e., a deductively closed system of empirical propositions) disappears. For Suppes, the meaning of the concept of model is the same in both mathematics and the empirical sciences.

   Scientific models tend to involve intricate mixtures of linguistic and mathematical elements. Typically, equations or other stylized syntactic items are used to *describe* the modeler's set-theoretic structure, intended to represent the target system in some idealized or approximate manner.

According to the structural empiricists, a workable conception of *validation of models of target systems* relies on (1) constructing *data models*, i.e., mathematical structures (matrices, histograms, trajectories, signal curves, etc.) that encode raw data from target system measurements in an idealized and rectified manner and (2) structure-preserving embeddings of these data models into the system's model. Accordingly, a model *correctly represents* its target system provided that all available data models are faithfully embeddable into it. We summarize the *structural empiricist* idea of data-based model validation by the following block diagram:

The great classical example of a set-theoretical predicate is given by the class of Kolmogorov's probability models. A set-theoretic triple $\langle \Omega, \mathscr{B}, \mathbf{P} \rangle$ is said to be a *probability model* provided that (1) Ω is a nonempty set, called the *sample space*; (2) $\mathscr{B}$ is a Boolean sigma algebra of subsets of Ω, interpreted as the algebra of events; and (3) $\mathbf{P}$ is a countably additive probability measure on $\mathscr{B}$. Here the customary domain of application of a theory is taken care of by the choice of a concrete probability model $\langle \Omega, \mathscr{B}, \mathbf{P} \rangle$. Differential manifolds of relativity theory, directed graphs constructed for kinship relations, and normal-form game-theoretic structures provide additional examples of structuralist-type models.

Models and Representations

In response to the question 'In virtue of what do mathematical models represent?' an often-discussed metaphysical answer is that mathematical models *represent* in virtue of nature itself being essentially mathematical and logical. This goes well with the contention that causal models represent causal relationships realized by the target system in a one-to-one fashion. The semantic view, held (among others) by Van Fraassen (1994), offers the following explicit *structuralist* account of representation:

> A mathematical model $\mathfrak{M}$ represents the target system S provided that $\mathfrak{M}$ is structurally isomorphic to S and $\mathfrak{M}$ is actually intended by the model builder to represent S.

A model $\mathfrak{M}$ is said to be *isomorphic* to the object of modeling (target system) S if the following conditions hold: (1) each basic constituent of S stands in a one-to-one relationship with a uniquely associated element in $\mathfrak{M}$ and of course conversely, (2) to every quantitative property of the target system S there corresponds a unique real number-valued function ear-marked by the model, and (3) each quantitative property relationship in S has a unique counterpart relationship in the model $\mathfrak{M}$.

A *structural realist* view of the model-target system relationship is outlined in the following block diagram:

For fairly obvious reasons (stemming from various idealizations, abstractions, and approximations), mathematical models constructed and used in science and engineering seldom meet the unreasonably strong structuralist definition of representation; the isomorphism requirement is usually relaxed in several ways by passing to a partial isomorphism or homomorphism of some sort.

In contemporary philosophy of science, structuralism is a leading approach to models and modeling, and it has several competing variants. The so-called *ontic* structuralists hold the view that mind-independent structure is all there is 'out there.' In more detail, according to French and Ladyman (2003), natural systems, phenomena, and processes should be conceptualized in purely structural terms. Any nonstructural understanding of the nature of empirical objects is metaphysical and unwarranted by the physical science itself. Since according to ontic structuralists systems and phenomena do *possess* structure but they themselves are *not* structure, models can be meaningfully thought of as representing their target systems via partial isomorphisms.

Another approach, called *epistemic* structuralism, defends the view that there is more to the world than its structure (e.g., objects, particles, events, and minds with natures and essences), but only structures are *knowable*. Structural *empiricism* argues that the structure of data and observables can be known, but denies that science should aim at knowing more. In brief, a target system's mathematical model is correct provided that the system's data structures are faithfully embeddable into the model. Thus, the model of a target system is *empirically adequate* if it correctly captures the structure of all system-generated data, made accessible via embedding maps.

Giere (1988, Chap. 3) and his followers argue that none of the above-mentioned mappings between models and target systems can capture the notion of representation. In their view, a model represents a target system just in case it is *similar* to the system. This substantially weakened requirement allows models to be only approximately the same as their target system. Unfortunately, a similarity relation-based account of representation does not fare any better than the structuralist isomorphism requirement, since in real-world modeling situations the notion of similarity applies to practically anything, until the modeler provides an explicit list of all its relevant aspects and degrees – an unworkable task in practice. More importantly, mathematical models tend to possess extra structure that their target systems do not have (e.g., the assumption of infinitely many agents in economic models or infinitely many gas atoms in

thermodynamic models), and conversely, for reasons of tractability, not all structures instantiated by a natural system are included in its model. This issue comes up also in the context of isomorphism, discussed earlier. Most philosophers share the view that the problem of representation requires further study.

Pluralism in Model Construction

Aside from technical tractability and approximation issues, there is no limit to the ways in which mathematical models may be constructed. Excluding the cases of unmanageable complexity and uninformative simplicity, models may employ any mathematical structure whatsoever, including deterministic, probabilistic, and stochastic variants and involving discrete, computable, measurable, continuous, or smooth real- or complex-valued quantities.

Conventional *top-down* model building (e.g., in physics and systems engineering) is characteristically based on first principles of an established scientific theory and constraints provided by the target system's idealized specification. Often from the simple 'initial' models more complex ones can be developed by gradually removing certain idealizations and abstractions. However, small increments in de-idealization or modeling realism are often paid for by significant increases of hard-to-manage mathematical complexity.

Since in biology, economics, and the social sciences in general, there is limited access to universal laws and empirical regularities, the styles of model construction vary widely. In particular, *bottom-up* or *data-driven* (e.g., time series generated) models tend to represent a relatively narrow spectrum of phenomena, while broadly intended models often suffer from low degrees of realism. In these contexts, the point of using a model is mostly to reveal its implications, explore its limits, and treat it as a guide in the development of epistemically more powerful models.

Validation of Mathematical Models

Although some mathematical models are built for general scientific research purposes (e.g., fictional, simulation, and 'toy' models), applications demand that models be validated by comparisons of their predictions with measurement data and results of other (valid) models. Model validation is a process of determining the degree to which a model under study is an accurate representation of its target system from the perspectives of its intended use and domain of application.

There are several problems that occupy the center stage in philosophical discussions of validation. First, since in view of idealizations a mathematical model is rarely correct in all subregions of its theoretically stipulated domain of application, in general, mathematical models cannot be proved valid. Second, in the case of complex models it would be too costly and time-consuming to determine whether or not the model is valid over its entire intended domain of application. Verifications are usually conducted until there is sufficient confidence that the model works well within its envisioned domain of application. Third, determining that the model is adequate in the context of several empirical tests does not guarantee that it is valid everywhere in its applicable domain. Model users' confidence that the model correctly represents the system is available only in degrees of probability. Unthoughtful model acceptance may to lead to two kinds of errors: (1) rejecting a good model, prompted by validation based on incorrect or biased data, or (2) accepting a bad model, endorsed by incomplete validation. Fourth, validation is often limited by the available class of observational data that are far from sufficient to showing that the model is correct in its entire range of application. Last, it is not true that good predictions can only be obtained from a model that is causally sound. Even near-perfect prediction–observation agreements over a wide range of observations may turn out to be a mere coincidence. Conversely, even good models can make bad predictions, as illustrated by Batitsky and Domotor (2007) in discussing models that are intended to represent the *chaotic* behaviors of simple target systems. In addition to robustness and sensitivity analyses and establishing as many connections between the model under study and its target system as possible, validation should also investigate the compatibility relations between the model and the target system's other accepted models.

In applications, it is far from sufficient to know that a dynamical model is *statistically* valid. The reason is that a statistically valid theoretical model may turn out to be *dynamically* (or qualitatively) invalid, meaning that it may fail to represent correctly the dynamical invariants of the target system (including equilibrium states, periodic, aperiodic, chaotic, or strange attractors, and their basins) under various choices of parameter values. Note that even if a dynamical model provides highly accurate predictions in its tested regions of intended use, it does not necessarily follow that the model is dynamically valid, since it may include spurious dynamics in untested regions that are also of interest. The target system's spectrum of actual behaviors remains largely unknown from the perspective of its representing model. Further observation and theoretical research may be needed to obtain a better knowledge about the dynamical invariants and characteristics of the system. Additional problems arise when the model fails to be valid in most parts of its domain of application. Deficiencies in the model may be traced to at least three starting conditions: (1) incorrectly derived equations (e.g., exclusion of decisive higher degrees of nonlinearity), (2) a coarse-grained choice of time and/or space discretization parameters that misses their pathological sensitivity to infinitesimal changes, and (3) reliance on data samples that are contaminated with gross errors.

Learning from Models

Models can serve as reliable vehicles of learning about target systems only if they correctly represent these systems. Thus, model-based knowledge acquisition about systems is intimately tied to the quality of representation. What is of particular interest here to philosophers of science is how a transfer of knowledge from a correctly representing model to its target system is achieved.

We have now surveyed several answers to the philosophers' basic questions about models. After these preliminaries, we now turn to a more detailed study of different types of mathematical models, furnished with a wide variety of algebraic and geometric structures. The underlying objective is

a characterization of the fundamental *duality* between equational and structuralist conceptions of mathematical models that most modern philosophers of science failed to recognize, and instead they continue to defend the idea that mathematical models are basically set-theoretic or category-theoretic structures. Unfortunately, the idea that mathematical models in science are structures that exist independently of and are unrelated to equational characterizations does not sit well with several contemporary mathematical results.

Symmetry Relationship Between Equational and Structuralist Conceptions of Mathematical Models

In the first part of the previous section, we drew the reader's attention to two opposing views about the nature of mathematical models. There is, however, a different approach to models that is even more important. In this alternative approach, the main idea is *unification* via *symmetry* or *duality*, based on a less familiar one-to-one correspondence between the classical (algebraic differential) equation-based and (geometric) structure-based conceptions of models. This unified view of models is attractive, because it is respectful of the algebraic and geometric aspects of models in a complementary fashion. Although this type of algebraic–geometric correspondence can be formalized in an abstract category-theoretic setting, we prefer a concrete illustration furnished by various pendulum models. We choose pendulum models as our running example because (1) most readers are intuitively familiar with the physical behavior of pendulums, (2) they are of historic and basic importance to philosophers of science, (3) it is possible to extend a pendulum model's domain of application by gradual de-idealization and structural enrichment, and (4) pendulum models are available for various physical modifications of classical pendulums, including coupled and double pendulums, extensible and forced pendulums, pendulums in a viscous fluid, relativistic and quantum pendulums, and so forth.

Recall that a simple undamped planar pendulum is classically modeled by the autonomous, deterministic, second-order nonlinear differential equation

$$\frac{d^2\theta}{dt^2} + \frac{g}{\ell}\sin\theta = 0$$

in which the time-dependent *unknown* quantity θ represents the pendulum's continuously varying angular displacement, measured from its downward vertical to the *arm* pivoting without friction on a shaft, to which a *bob* of tiny size with mass m is attached at its swinging end. Constant g denotes the homogeneous local gravitational acceleration acting on the pendulum's bob downward and parameter ℓ captures the length of the pendulum's idealized weightless and perfectly rigid arm. These coefficients are needed for individuating the target pendulum (modulo duplicate relationships) in its *classical* gravitational ambience. The foregoing nonlinear pendulum equation is derived from Newton's second law of motion and the pendulum's accompanying *idealizing scenario*, involving significant idealizations of friction, torque, resistance, and elasticity. We mention in passing that in addition to the pendulum, the nonlinear equation above also represents the motions of many other physical systems. However, the accompanying physical interpretations are different.

The first term in the equation above encodes inertia, and the second term stands for the impact of gravity. Recall that the pendulum's arm is suspended from a pivot point around which it oscillates or rotates in a vertical plane without surface resistance and forcing, so that there are no extra *additive* terms in the equation for these causes. Recall that generally a model is a simplified mathematical representation of a real-world system of interest for designated scientific purposes. Although the target system has many important features, not all of them can and should be included in the model for reasons of tractability and limited epistemic import. Those features that are included often involve drastic idealizations known to be empirically false.

Solutions to the foregoing nonlinear pendulum equation are continuously twice differentiable, time-dependent, real-valued functions of the form $\theta : \mathbb{T} \to \mathbb{S}$ (intended to capture the pendulum bob's time-varying angular positions in all regimes), where $\mathbb{T}$ denotes a designated continuum-time domain, usually isomorphic to the additive group of reals, and the less familiar notation $\mathbb{S} =_{df} \mathbb{R}_{/2\pi\mathbb{Z}} = \mathbb{R} \bmod 2\pi$ is reserved for the circle group of reals, whose underlying set is isomorphic to the half-open interval $[0,2\pi]$. In this way, a given solution θ assigns to each time instant t a unique angle $\theta(t) = \xi$ in $\mathbb{S}$, interpreted as the bob's angular position at t. Technically, all exact (nonelementary) solutions of the pendulum equation are specified analytically by Jacobian elliptic sine functions, and the period is expressed in terms of the so-called complete elliptic integral of the first kind. Therefore, for any given initial condition the corresponding solution can only be obtained numerically, albeit with arbitrary accuracy, using rapid computer calculations. An alternative approach is a passage to *discrete-time difference* equations of the form

$$\theta_{n+1} - 2\theta_n + \theta_{n-1} + \frac{g}{l}(\Delta t)^2 \sin\theta_n = 0$$

where Δt is the length of the time interval, serving as the elementary step of the difference scheme, and for any natural number n, value $\theta_n =_{df} \theta(n\Delta t)$ refers to the bob's approximate angular position at time $n\Delta t$. To improve the accuracy of calculations, modelers should choose very small values of Δt.

To link the *classical* pendulum equation and its solutions to a corresponding *structural* description of the pendulum's dynamical behavior, we must reduce the original equation to a pair of first-order autonomous differential equations of the form

$$\frac{d\theta}{dt} = v \qquad [1]$$

$$\frac{dv}{dt} = -\frac{g}{\ell}\sin\theta \qquad [2]$$

Evidently, their solutions come in pairs of functions that are conveniently combined by set-theoretic pairing into a single solution of the form $\theta; v : \mathbb{T} \to \mathbb{S} \times \mathbb{R}$ that assigns to each instant of time t a unique angular position-angular velocity pair $[\theta;v](t) = (\theta(t), v(t))$, interpreted as the pendulum's *state* of motion at t. We now have the mathematical

means at hand to encode the pendulum's physical behavior *geometrically*. In particular, the pendulum's two-dimensional cylinder-shaped topological *state space* $\mathbb{S} \times \mathbb{R}$ (generated by the circle $\mathbb{S}$) and certain smooth curves therein, corresponding to state-parametrized solutions and forming the target system's so-called *phase portrait*, provide a complete *geometric* as opposed to an *algebraic* understanding of the pendulum's possible behaviors.

We turn now from the solutions of the foregoing equations to a uniquely associated continuously differentiable *dynamical transition map* of the form

$$\mathsf{T} : \mathbb{T} \times (\mathbb{S} \times \mathbb{R}) \rightarrow \mathbb{S} \times \mathbb{R}$$

defined by $\mathsf{T}_t(\xi, v) =_{df} \langle \theta_{\xi,v}(t), v_{\xi,v}(t) \rangle$ for all time instants t, angles ξ, and velocities v. We may regard $\mathsf{T}_t(\xi, v)$ as a formal encoding of the pendulum's 'final' state into which the 'initial' state (ξ, v) evolves after time t. Here it is important to notice that, although there is a plentiful supply of solutions to the pendulum equations, they have to be individuated by states. For example, in view of the equality $\langle \theta_{\xi,v}(0), v_{\xi,v}(0) \rangle = (\xi, v)$, the state (ξ, v) singles out the solution $\theta_{\xi,v}; v_{\xi,v}$ (used in the definition above) and therefore the *trajectory* or *orbit* $\{\mathsf{T}_t(\xi, v) | t \in \mathbb{T}\}$ of (ξ, v) in $\mathbb{S} \times \mathbb{R}$. Trajectories densely fill the entire cylindrical state space and serve as prominent geometric tools in the study of pendulum motions.

It is easy to verify that the induced time-indexed *dynamical maps*

$$\mathsf{T}_t : \mathbb{S} \times \mathbb{R} \rightarrow \mathbb{S} \times \mathbb{R}$$

satisfy the following functional equations for all time instants t and t' in $\mathbb{T}$:

1. *Identity property*: $\mathsf{T}_0 = \mathsf{I}$ (identity transformation) and
2. *Group property*: $\mathsf{T}_{t+t'} = \mathsf{T}_t \cdot \mathsf{T}_{t'}$.

Dynamical maps completely determine the time evolution of the pendulum's motion in the following way: if we know that the pendulum is in state (ξ, v) at time $t = 0$, then it is in state $\mathsf{T}_t(\xi, v)$ at time t. Needless to add, in general, knowledge of T_t is only approximate. As the reader may have already realized, we now have a canonical structuralist *dynamical model* $\langle \mathbb{S} \times \mathbb{R}, \mathsf{T} \rangle$ of the classical pendulum – a semantic counterpart or dual of the pendulum equations. In general, dynamical models are given by an underlying (topological, measurable, etc.) state space and a time-indexed family of transformations (dynamical maps) thereon, satisfying the functional equations.

An impressively large class of deterministic dynamical models arises from autonomous systems of ordinary or partial differential equations by simple state-parametrizations of their solution spaces. Conversely, since $\mathsf{T}_t(\xi, v)$ is a state-parametrized solution of the pendulum equations, it automatically determines these equations. In general, the (vector) differential equation

$$\frac{\mathrm{d}\mathsf{T}_t}{\mathrm{d}t} = \mathbf{A}\mathsf{T}_t$$

corresponding to a *dynamical model* $\langle \mathbb{S} \times \mathbb{R}, \mathsf{T} \rangle$ is reconstructed from the analytic properties of T_t and those of a suitable operator **A**. For additional details, see Engel, Nagel (2000), and the references therein.

Structuralists argue that the particular system of classical equations that generates the dynamical transition map is of secondary concern. In a dynamical model, comprising a state space and dynamical maps, each state space point is an abstract, information-bearing encoding of the target system's physical mode of being at a given time. Assuming that the system under consideration has a state structure, its adequate state space model comes with a state space comprising points that are presumed to contain *complete information* about the past history of the system, relevant to its future behavior. Thus, if the target system's instantaneous physical state – encoded by a point in its representing state space – is known, then the system's subsequent temporal evolution can be predicted with the help of the model's dynamical maps, without any additional knowledge of what has happened to the system. The dynamical map need not be continuous or smooth. It can also be measurable, computable, discrete, and local (i.e., only partially defined). The foregoing structuralist definition of a deterministic dynamical model fits well into the conceptual framework of category theory that provides a formal *adjointness* account of interplay between dynamical models and received-view equations.

An obvious question now arises: what is duality in the case of probability models? Thanks to the so-called Riesz and spectral representation theorems, the question is not hard to answer. Each probability model $\langle \Omega, \mathscr{B}, \mathbf{P} \rangle$ comes with its von Neumann algebra $\mathfrak{L}_\infty(\Omega, \mathscr{B}, \mathbf{P})$ of bounded real-valued random variables of the form $X : \Omega \rightarrow \mathbb{R}$, modulo **P**-measure zero – meaning that random variables X and X' are viewed as equal whenever the equality $\mathbf{P}(\{\omega | X(\omega) \neq X'(\omega)\}) = 0$ holds. And every abstractly given commutative von Neumann algebra is isomorphic to an algebra of this type. Thus, as common in statistics, one can start with a probability model and then switch to the induced algebra of random variables, their expectations, and equations between them or proceed in the reverse direction.

We digress briefly to consider data models. Since experimental data and numerical analysts' calculations tend to come only with limited degrees accuracy (due to measurement errors and round-off operations), it is necessary to consider selected *finite* configurations of states of a parent dynamical model that are conveniently viewed as the underlying *discrete state spaces* of data models. In the spirit of state space discretization algorithms, a region of interest (e.g., a basin of attraction of the model's phase portrait) in the model's state space is subdivided into cells of appropriate mesh size. Each cell comes with a designated representative state, usually calculated by suitable averaging. Dynamical maps on discrete state spaces are then determined by temporal transitions between cell representatives. Discretized dynamical models associated with state space regions provide the formal meeting ground for measurement results and calculated predictions. From a structural empiricist point of view, data models are finitary variants of discretized dynamical models, intended to validate the parent model. Large families of compatible data models can be used to 'cover' the parent dynamical model's domain of

intended application, as illustrated in the following simplified block diagram:

If the *covering system* of data models obtained from various measurements locally agrees with the parent dynamical model's domain of application, that is to say, each data model in the covering system is embeddable into the parent model to within antecedently specified errors, then the parent model is said to be *empirically adequate* relative to the cover. Anyone who is familiar with the chaotic behavior of certain systems quickly realizes that covering chaotic regimes by deterministic data models is ineffective and a passage to carefully designed statistical data models (e.g., built from histograms) becomes necessary.

At this stage, we widen the structuralist point of view somewhat. Models in contemporary mathematical physics are based on the notion of *observable*, intended to encode a target system's quantitative property of interest. In simple situations, model builders assume that (1) observables are real-valued functions, possessing values that can be approximately ascertained by reading an appropriately chosen measuring instrument and (2) their algebraic nature is best expressed by a suitable quantity algebra. Thus, in our running example instead of describing the pendulum's possible motions geometrically in terms of state space trajectories, we turn to a more effective quantitative description of pendulum dynamics, using an associated algebra of observables. The all-important observable quantity is the pendulum's total energy (Hamiltonian) function $\mathsf{E} : \mathbb{S} \times \mathbb{R} \to \mathbb{R}$, defined by the sum of kinetic and potential energy functions

$$\mathsf{E}(\xi, v) \underset{df}{=} \frac{m\ell^2}{2} v^2 + mg\ell(1 - \cos\xi)$$

at each pendulum state (ξ, v). The total energy function is truly significant because (1) the pendulum equation can be reconstructed from it by Hamiltonian differentiation and (2) each curve of the phase portrait corresponds to a different energy value and thus to a different initial condition. Furthermore, it is well-known that contingently on the possible values E of the energy function E with respect to its *critical* level $2mg\ell$ (required for the bob to reach the top point on the vertical), there are three major types of pendulum motion that the experimenter can observe:

1. If $E < 2mg\ell$, then there is insufficient energy available and the pendulum's bob is performing simple oscillations around the minimum. Larger energy values E specify correspondingly larger closed (quasi) elliptical orbits in the pendulum's state space.
2. If $E > 2\,mg\ell$, then the bob makes complete unidirectional rotations ad infinitum. These large energy values individuate open orbits.
3. If $E = 2\,mg\ell$, then the pendulum's bob has exactly the energy needed to reach the top vertical position, and it will remain in this unstable position until the slightest perturbation sends it into one of the two trajectories intersecting at this point. The associated 'border' trajectory $\{(\xi, v | \mathsf{E}(\xi, v)) = 2mgl\}$ is called a *separatrix*, since it separates the two previous regimes (oscillations and rotations) and accordingly divides the state space into disjoint regions of closed and open orbits. From a physical standpoint, separatrix is the trajectory in $\mathbb{S} \times \mathbb{R}$ that encodes the bob's motion with exactly enough energy for it to reach the top unstable (hyperbolic) fixed point, taking an infinite amount of time to get there.

These kinds of considerations lead to the conclusion that equations in a differential paradigm are necessary for formal derivations and calculations, while their semantic counterparts are crucial in geometric interpretations and embodiment of physical content.

Before leaving this section, we make a few technical remarks about observables and their dynamical models. It is easy to see that the bob's velocity $\boldsymbol{v} : \mathbb{S} \times \mathbb{R} \to \mathbb{R}$ is also an observable quantity, if viewed as the second projection map, defined by $\boldsymbol{v}(\xi, v) = v$. A very similar approach applies also to angular displacement $\boldsymbol{\theta}$. Since these and other observables can be added and multiplied, they automatically form an algebra. Let $\mathbf{C}(\mathbb{S} \times \mathbb{R})$ be the algebra of all continuous observables on the cylindric topological state space $\mathbb{S} \times \mathbb{R}$. Conceptually, the topological structure of the state space is now traded for an algebraic structure in a unified manner. Since angular position, angular velocity, and other measurements are seldom perfectly accurate, we need a second structural component that handles all uncertainties associated with information acquisition about quantities. Let $\mathbf{S}(\mathbb{S} \times \mathbb{R})$ be the convex space of all normalized positive linear functionals of the form $\varepsilon : \mathbf{C}(\mathbb{S} \times \mathbb{R}) \to \mathbb{R}$. Since for any quantity Q the value $\varepsilon(\mathsf{Q})$ of ε is the *expectation* of Q, it makes good sense to interpret the abstract functional ε as the target system's *statistical state*. All this is based on the so-called spectral theorem that states that each statistical state has a unique expectation integral representation relative to a probability measure on some measurable space. In sum, quantity algebras and associated convex spaces of statistical states allow model builders to construct mathematical models in an admittedly abstract albeit highly unified manner. More details on applications of quantity algebras to measurement theory may be found in Domotor and Batitsky (2009).

In particular, each structuralist *topological state space dynamical model* $\langle \mathbb{S} \times \mathbb{R}, \mathsf{T} \rangle$ induces an *algebraic dynamical model* $\langle \mathbf{C}(\mathbb{S} \times \mathbb{R}), \mathsf{T}^* \rangle$ of observables, defined by the operator composition $\mathsf{T}^*_t(\mathsf{Q}) \underset{df}{=} \mathsf{Q} \circ \mathsf{T}_t$ for all quantities Q and time instants t. Concretely, in view of $\mathsf{E}_t(\xi_0, v_0) = \mathsf{E}(\xi_t, v_t)$, where $(\xi_t, v_t) = \mathsf{T}_t(\xi_0, v_0)$, the energy quantity can now be considered as time dependent and evolving. In the same spirit, we can also consider a statistical dynamical model induced on statistical states $\mathbf{S}(\mathbb{S} \times \mathbb{R})$.

The passage from an underlying state space dynamical model to the algebraic dynamical model of quantities becomes necessary when the modeler can no longer ignore the ways in which measurements are performed on the systems under study. When an observable is measured, its values are obtained only with a certain probability. Unfortunately, the structuralists' state space dynamical model represents the target system's behavior in itself, without providing the necessary conceptual ingredients for physical measurement and accompanying statistical properties. Discretized algebraic dynamical models of quantities and associated algebraic data models are based on algebraic dynamical models induced by *discrete* state space dynamical models. Topological state space dynamical models suffer from a fundamental inadequacy in the case of *chaotic* target systems, since they focus only on the deterministic side of behavior and the statistical aspects are ignored. However, in these complex scenarios only statistical methods are effective. We shall not give any further details. The technical aspects of these scenarios are studied by Lasota and Mackey (1994).

Structural Enrichments, Perturbations, and Other Modifications of Mathematical Models

In applications of mathematics to real-world problems, there is a frequent requirement of significant flexibility in mutating models by various combinations, de-idealizations, and structural enrichments. As an illustrative background, we shall continue to use the running example of pendulums.

We start with two examples involving a combination and mutation of nonlinear pendulum models. First, consider a double pendulum. It consists of one pendulum attached to another, so that it has two arms and two balls, where the second arm is attached to the first arm's ball. In the case of large displacements, a double pendulum is famously chaotic, but for small oscillations it behaves in simple predictable ways. Double pendulum equations are derived from Newton's second law of motion and simple background conditions, dictated by the idealizing scenario. Structuralists represent the double pendulum by the product dynamical model $\langle \mathbb{S}^2 \times \mathbb{R}^2, \mathsf{T} \otimes \mathsf{T}' \rangle$ with state space $\mathbb{S}^2 \times \mathbb{R}^2 \cong (\mathbb{S} \times \mathbb{R}) \times (\mathbb{S} \times \mathbb{R})$ and a product dynamical map $\mathsf{T} \otimes \mathsf{T}'$ obtained from the constituent dynamical maps of each pendulum and the coupling relation, responsible for chaotic regimes.

Our other example addresses de-idealization cases of pendulum damping and forcing by various mechanisms. Elementary treatments usually assume that the damping torque is directly proportional to the angular velocity. This so-called *linear damping* is captured quite simply by adding an extra term to the original nonlinear pendulum equation, so that now we have

$$\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2} + \alpha\frac{\mathrm{d}\theta}{\mathrm{d}t} + \frac{g}{\ell}\sin\theta = 0$$

where the damping coefficient α in the linear damping term is assumed to be positive. In order to achieve a better representation of friction, quadratic and other terms may be added to the initial pendulum equation, making the computation of approximate solutions increasingly harder. Pendulums driven by constant or periodic external forces and their combinations have mathematical significance in adding extra complexity to model construction. The question now arises as to whether or not less idealized, and hence more complete and more accurate models are decisively better to work with than simpler, less complicated models. As we have already indicated, model accuracy and overall adequacy is not achievable by a simple increase in structural complexity. The reasons are buried in inaccuracies in background conditions, limited knowledge of too many parameter values, and escalating round-off errors in calculating predictions based on complex models. Since complex models tend to lead to resource-bounded and hence significantly less accurate results than those obtained from simpler models, their complexity must be commensurate with background information available in their applications.

In many applications, the same basic pendulum differential equation drops out of a wholly different idealizing scenario of, say, a coupled mass-spring system, consisting of a (point) mass attached to a spring at one end, where the other end of the spring is tied to a fixed frame. Other prominent examples of systems, whose dynamical behavior is also modeled by 'pendulum equations', include electric circuits, chemical reactions, and interacting biological populations with oscillatory behaviors. Of course, in each application, the indeterminate and individuating parameters are interpreted differently.

A whole new field of mathematical model construction is opened up with the introduction of relativistic and quantum aspects of a target system. In the special case of a simple pendulum, we already know that the solution space of the nonlinear pendulum equation includes many relativistically forbidden solutions that encode physically impossible behaviors – individuated by the pendulum's *superluminal* angular velocities. The key idea here is that in the absence of complete knowledge of the model's empirical *domain of applicability*, a researcher may be in an epistemic danger of trying to physically interpret (in terms of behavior) some of the solutions – countenanced by the model, which are actually meaningless in the physical world.

To remedy the situation, the foregoing classical simple pendulum model must be extended to the *relativistic* case (studied, e.g., by Erkal (2000)), having the form

$$\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2} + \left(1 - \left(\frac{\ell}{c}\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\right)\frac{g}{\ell}\sin\theta = 0$$

where parameter c denotes the speed of light. Because formal models usually possess limited empirical domains of applicability, in comprehensive treatments of target system behavior several different, closely related models may become necessary.

Real-world systems tend to have many representing models, and these models often possess a surplus content, which supports their mutations and extensions in unexpected ways. For example, in the presence of randomness or 'noise', a classical *stochastic pendulum equation* provides the most appropriate representation of randomly perturbed motion, observed (say) on a pendulum attached to a vibrating ceiling. A typical model of the behavior of simple pendulums affected by 'noise' is

presented by the following pair of stochastic differential equations:

$$\frac{d\Theta}{dt} = \Upsilon \qquad [3]$$

$$\frac{d\Upsilon}{dt} = -\frac{g}{\ell}\sin\Theta + \epsilon\Upsilon\frac{dW}{dt} \qquad [4]$$

where Θ denotes the 'unknown' stochastic angular position, i.e., a time-dependent angle-valued random variable; Υ symbolizes the 'unknown' stochastic angular velocity, i.e., a time-dependent real-valued random variable; the noise parameter $\epsilon > 0$ is intended to capture the strength of random noise; and W is a stochastic (e.g., Wiener) process, encoding the pendulum's random erratic motion on a microscale. In this model, realizations of trajectories, representing the pendulum's motion in a sample, are jagged in proportion to the value of noise parameter ε. Putting the earlier described constructions together we envision the construction of stochastic dynamical models for double pendulums, relativistic pendulums, and so forth.

We can also consider the case in which the stochastic component has a parametric perturbation form, captured by the stochastic differential equation

$$\frac{d^2\Theta}{dt^2} + \left(\frac{g}{\ell} + \epsilon W\right)\sin\Theta = 0$$

in which the 'noise' affects the period of oscillation.

Importantly, although in recent years efforts have been made to come to grips with the conceptual side of structuralist dynamical models, practically all stochastic models are presented in an equational form.

In conclusion, in the absence of other options it is too early to tell which of the two conceptions (i.e., equational vs. structural) of mathematical models will prove more important in the future development of models in science. However, it is clear already that the duality between equations and solution-induced structures has significantly deepened our understanding of the nature of mathematical models, their construction, and validation.

Abstract

The article reviews the field from a historical perspective, starting from the works of Fechner and Thurstone, and outlining the basic theoretical concepts in four traditional areas: learning, psychophysics, measurement and choice, and response times. More recent topics that have emerged from these areas are also briefly mentioned together with their most prominent contributors.

Introduction

Mathematics has been used in psychology for a long time, and for different purposes. When William James (1890/1950) writes,

$$\text{Self-esteem} = \frac{\text{Success}}{\text{Pretensions}}$$

he is using mathematical notation metaphorically. Because no method is provided to measure the three variables, the equation cannot be taken literally. James means to convey, by a dramatic formula, the idea that if your pretensions increase without a corresponding increase of your success, your self-esteem will suffer. Such usages of mathematics, which Miller (1964) calls 'discursive,' can be found in psychological discourse at least since Aristotle. Despite their historical interest, we shall not review such metaphorical uses of mathematics here (see instead, Boring, 1950, or Miller, 1964).

In this article, we reserve the term *mathematical psychology* to the elaboration and the testing of mathematical theories and models for behavioral data. In principle, such a theory entails an economical representation of a particular set of data in mathematical terms, where 'economical' means that the number of free parameters of the theory is substantially smaller that the number of degrees of freedom in the data. In that sense, mathematical psychology plays for behavioral data the role that mathematical physics or mathematical biology play for physics or biology, respectively. In the best cases, the theory is cast in probabilistic terms and is testable by standard statistical methods. The large majority of such mathematical theories for behavioral data have emerged from four partially overlapping traditional fields: psychophysics, learning, choice, and response times. Each field will be outlined from the standpoint of the prominent mathematical models that have been proposed. Other topics to which mathematical psychologists have devoted much work are also mentioned.

The Precursors: Fechner and Thurstone

Gustav Theodor Fechner (1801–87; see Boring, 1950) was by training an experimental physicist with a strong mathematical background. While his interests were diverse and his contributions many, ranging from experimental physics to philosophy, we only consider him here as the founder of psychophysics. His main purpose was the measurement of 'sensation' in a manner imitating the methods used for the fundamental scales of physics, such as length or mass. Because 'sensation' could not be measured directly, Fechner proposed to evaluate the difference between the 'sensations' evoked by two stimuli by the difficulty of discriminating between them.

To be more specific, we introduce some notation. We write x, y, and so forth for positive real numbers representing physical intensities measured on some ratio scale, such as sound pressure level. Let $P(x, y)$ be the probability that stimulus x is judged to be louder than stimulus y. Cast in modern terms (cf Luce and Galanter, 1963; Falmagne, 1985/2002) Fechner's idea amounts to finding a real valued function u defined on the set of physical intensities, and a function F (both strictly increasing and continuous) such that

$$P(x, y) = F[u(x) - u(y)]. \qquad [1]$$

This equation is supposed to hold for all pairs of stimuli (x, y) such that $0 < P(x, y) < 1$ (subjectively, x is close to y). If such an equation holds, then the function u can be regarded as a candidate scale for the measurement of 'sensation' in the sense of Fechner. A priori, it is by no means clear that a scale u satisfying [1] necessarily exists. A necessary condition is the so-called *Quadruple Condition*: $P(x, y) \leq P(x', y') \Leftrightarrow P(x, x') \leq P(y, y')$, where the equivalence is assumed to hold whenever the four probabilities are defined. In the literature, the problem of constructing such a scale, or of finding sufficient conditions for its existence, has come to be labeled *Fechner's problem*. An axiomatic discussion of Fechner's problem can be found in Falmagne (1985/2002; see also Krantz et al., 1971).

For various reasons, partly traditional, psychophysicists often prefer to collect their data in terms of discrimination thresholds, which can be obtained as follows from the discrimination probabilities. We define a *sensitivity function* $\xi : (y, v) \mapsto \xi_v(y)$ by the equivalence: $\xi(y, v) = x \Leftrightarrow P(x, y) = v$. The *Weber function* $\Delta : (y, v) \mapsto \Delta_v(y)$, (y) is then defined by the equation $\Delta_v(y) = \xi_v(y) - \xi_{0.5}(y)$. (Weber, E.E. (1795–1878), a colleague of Fechner, professor of anatomy and physiology at Leipzig.). A representation of these fundamental concepts of classic psychophysics is given in **Figure 1**, in a special case where $P(y, y) = 0.5$. For each value of y, the S-shaped function $x \mapsto P(x, y)$ is called a *psychometric function*.

Starting with Weber himself, the Weber function Δ has been investigated experimentally for many sensory continua. In practice, $\Delta_v(y)$ is estimated by stochastic approximation

Figure 1 The Weber function Δ in the case where $P(y, y) = 0.5$ for all stimuli y; thus $\xi_{0.5}(y) = y$. The S-shape function $x \mapsto P(x, y)$ is referred to as a *psychometric function*.

(cf Robbins and Monro, 1951; Wasan, 1969; Levitt, 1970) for one or a few *criterion* values of the discrimination probability ν and for many values of the stimulus y. A typical finding is that, for stimulus values in the midrange of the sensory continuum and for some criterion values ν, $\Delta_\nu(y)$ grows approximately linearly with y, according to the equation:

$$\Delta_\nu(y) = yC(\nu), \qquad [2]$$

where C is a function depending on the criterion. The label *Weber's law* is attached to this equation. It is easily shown that [2] is equivalent to the homogeneity equation $P(\lambda x, \lambda y) = P(x, y)$, $(\lambda > 0)$, which in turn leads to $P(x, y) = H(\log x - \log y)$, with $H(s) = P(e^s, 1)$. This means that the function u in [1] has the form

$$u(y) = A \log y + B, \qquad [3]$$

where the constants $A > 0$ and B arise from uniqueness considerations for both u and F. Equation [3] has been dubbed *Fechner's law*. Our discussion indicates that, in the framework of (reffechone), Weber's law and Fechner's law are equivalent. Much of psychophysics evolved from Fechner's ideas.

The most durable contribution of Leon Louis Thurstone (1887–1955) to mathematical psychology is his *Law of Comparative Judgments* (Thurstone, 1927a, b; see Bock and Jones, 1968), a cornerstone of binary choice theory closely related to [1] of Fechner's problem. Thurstone supposed that a subject confronted with a choice between two alternatives x and y (where x, y are arbitrary labels and do not necessarily represent numerical values), makes a decision by comparing the sampled values of two random variables $\mathbf{U}_x$ and $\mathbf{U}_y$ associated to the alternatives. Suppose that these random variables are independent and normally distributed, with means $\mu(x)$, $\mu(y)$, and variances $\sigma^2(x)$, $\sigma^2(y)$, respectively. Denoting by Φ the distribution function of a standard normal random variable and with $\mathbb{P}$ standing for the probability measure, this leads to

$$P(x, y) = \mathbb{P}(\mathbf{U}_x > \mathbf{U}_y) = \Phi\left(\frac{\mu(y) - \mu(y)}{\sqrt{\sigma^2(x)^2 + \sigma^2(y)^2}}\right). \qquad [4]$$

Assuming that all the random variables have the same variance $\sigma^2 = \alpha^2/2$, we obtain

$$P(x, y) = \Phi(u(x) - u(y)), \qquad [5]$$

with $u(x) = \mu(x)/\alpha$ and $F = \Phi$, a special case of [1]. Equations [4] and [5] are called *Case III* and *Case V* of the *Law of Comparative Judgments*, respectively. Thurstone's model has been widely applied in psychophysics and choice. Other models in the same vein have been proposed by various researchers (e.g., Luce, 1959; Luce and Suppes, 1965). Thurstone's other important contributions are in learning theory (e.g., Thurstone, 1919), and especially Multiple-Factor Analysis (e.g., Thurstone, 1947).

The Beginning: Mathematical Learning Theory

Two articles mark the beginning of mathematical psychology as a distinguished research field: one by Estes (1950), *Toward a Statistical Theory of Learning*, and another by Bush and Mosteller (1951), *A Mathematical Model for Simple Learning*. These works were the highlights of a movement spearheaded by R. R. Bush and R. D. Luce at the University of Pennsylvania, and R. C. Atkinson, W. K. Estes, and P. Suppes at Stanford, which set out to formalize mathematical learning theories in terms of stochastic processes, and especially, Markov processes (cf Bharucha-Reid, 1960; Parzen, 1994). There were good reasons for such a development at that time. The previous decade had been plagued by fruitless controversies concerning the basic mechanisms of learning. While a considerable experimental literature on learning was available (cf Hilgard, 1943), the statistical tools in use for the analysis of the data were poor and the prominent theories ambiguous. When mathematics was used, it was metaphorically. Moreover, the scope of the theories was ambitious, covering a vast class of experimental situations loosely connected to each other conceptually. A typical example of such an endeavor is Hull (1943). By contrast, the Markov models developed by Bush, Estes, and their followers were designed for specific experimental situations. Under the influence of Suppes, a philosopher of science from Stanford who played a major role in the development of mathematical psychology, these models were often stated axiomatically. As a consequence, the predictions of the models could in many cases be derived by straightforward mathematical arguments. Two classes of models were investigated.

Finite State Markov Chains

In these models, the basic idea is that the subject's responses in a learning experiment are the reflection of some internal states, which coincide with the states of a finite Markov chain. The transitions of the Markov chain are governed by the triple of events (stimulus, response, reinforcement) occurring on each trial. In many situations, the number of states of the Markov chain is small. We sketch a simple case of the so-called *one-element model*, in which the chain has only two states that we denote by N and K. Intuitively, N stands for the 'naive' state, and K for the 'cognizant' state. On each trial of the experiment, the subject is presented with a stimulus and has to provide a response, which is either labeled as C (correct) or

as F (false). For example, suppose that the subject has to identify a rule used to classify some cards into two piles. Say, a drawing on each card has either one or two lines, which can be either both straight or both curved, and either both vertical or both horizontal. The subject must discover that all the cards with curved lines, and only those, go on the left pile. The subject is told on each trial whether the chosen pile is the correct one.

In words, the four axioms of the model are as follows: [M1] The subject always begins the experiment in the naive state N; [M2] the probability of a transition from the naive state N to the cognizant state K is equal to some parameter $0 < \theta < 1$, constant over trials, regardless of the subject's response; [M3] in state N, the probability of a correct placement is equal to a parameter $0 < \alpha < 1$, constant over trials; [M4] in state K, the response is always correct. The derivation of the model can either be based on a two-state Markov chain with state space $\{N, K\}$, or on a three-state Markov chain with state space $\{(N, C), (N, F), (K, C)\}$ (where N, K denote the subject's states and C, F the responses). In either case, the derivations are straightforward. Notice that, from axioms [M1] and [M2], the trial number of the occurrences of the first K state has a geometric distribution with parameter θ. Writing $\mathbf{S}_n$ and $\mathbf{R}_n$ for the cognitive state and the response provided on trial $n = 0, 1, \ldots$ (thus, $\mathbf{S}_n = N, K$ and $\mathbf{R}_n = C, F$), we get easily, for $n = 0, 1, \ldots$,

$$\begin{aligned} &\mathbb{P}(\mathbf{S}_n = N) = (1-\theta)^n, \\ &\mathbb{P}(\mathbf{R}_n = C|\mathbf{S}_n = N) = \alpha \\ &\mathbb{P}(\mathbf{R}_n = C|\mathbf{S}_n = K) = 1 \\ &\mathbb{P}(\mathbf{R}_n = C) = 1-(1-\theta)^n(1-\alpha), \\ &\text{which implies, with } p_n = \mathbb{P}(\mathbf{R}_n = C), \\ &p_{n+1} = (1-\theta)p_n + \theta. \end{aligned} \qquad [6]$$

A strong prediction of this model is that the number of correct responses recorded before an error occurring on trial number $(n+1)$ should be binomially distributed with parameters α and n (i.e., all the subjects' responses have been generated by the naive state). This prediction is surprisingly difficult to reject, at least in some situations (Suppes and Ginsburg, 1963).

Linear Operators Models

To facilitate the comparison, we take the same concept identification experiment as above, involving the classification of cards into two piles, and we consider a simple representative of this class of models. As before, we denote by $\mathbf{R}_n$ the response on trial n. We take as the sample space the set of all sequences $(\mathbf{R}_0, \mathbf{R}_1, \ldots, \mathbf{R}_n, \ldots)$, with $\mathbf{R}_n = C, F$ for $n = 0, 1, \ldots$. We also define

$$p_{w,0} = \mathbb{P}(\mathbf{R}_0 = C),$$

$$p_{w,n} = \mathbb{P}(\mathbf{R}_n = C|\mathbf{R}_{n-1}, \ldots, \mathbf{R}_0), \quad n = 1, 2, \ldots.$$

Let $0 < \theta < 1$ be a parameter. The axiom of the model has two cases, for $n = 0, 1, \ldots$,

$$[\text{L1}] \quad p_{w,n+1} = (1-\theta)\, p_{wn} + \theta \quad \text{if } \mathbf{R}_{n-1} = F,$$

$$[\text{L2}] \quad p_{w,n+1} = p_{wn} \quad \text{if } \mathbf{R}_{n-1} = C.$$

Thus, the model has the two parameters $p_{w,0}$ and θ, and learning occurs only when false responses are provided. As in the case of the finite Markov chains models, many predictions could be derived from such models, which could then be tested on the type of learning data traditionally collected by the experimenters. For both classes of models, the results of such enterprises were often quite successful. Nevertheless, the interest for such models waned during the 1960s, at least for learning situations, because researchers gradually realized that their simple mechanisms were far too primitive to capture all the intricacies revealed by more sophisticated analyses of learning data (see especially Yellott, 1969). General presentations of this topic can be found in Atkinson and Estes (1963) or Atkinson et al. (1965) for the finite state Markov learning models, and in Estes and Suppes (1959) or Sternberg (1963) for the linear operator models. A mathematical discussion of Markov processes for learning models is contained in Norman (1972).

Despite the partial failure of these models to provide a satisfactory detailed explanation of traditional learning data, their role was nevertheless essential in the introduction of modern probability theory (in particular stochastic processes) and axiomatic methods in theoretical psychology, and in promoting the emergence of mathematical psychology as a field of research. In recent years, a renewed interest in learning theory has appeared from the part of some economists.

Psychophysics

The main research topics in psychophysics can be traced back to the ideas of Fechner and Thurstone outlined in the first section of this article. Fechner's method of measuring sensation is indirect and based on the difficulty of discriminating between two stimuli. Under the impetus of S. S. Stevens, a psychologist from Harvard, different experimental methods for 'scaling' sensation became popular.

Direct Scaling Methods

In the case of the *magnitude estimation* method, Stevens (1957) asked subjects to make direct numerical judgments of the intensities of stimuli. For example, a subject may be presented with a pure tone of some intensity x presented binaurally, and would be required to estimate the magnitude of the tone on a scale from 1 to 100. Typically, each subject would only be asked to provide one or a couple of such estimations, and the data of many subjects would be combined into an average or median result, which we denote by $\phi(x)$. In many cases, these results would be fit reasonably well by the so-called *Power law* $\phi(x) = \alpha x^\beta$ or such variants as $\phi(x) = \alpha x^\beta + \gamma$ and $\phi(x) = \alpha(x-\gamma)^\beta$. In the *cross modality matching* method, the subject is presented with a stimulus from one sensory continuum (e.g., loudness), and is required to match its intensity with that of some other stimulus, from a different sensory continuum (e.g., brightness). Power laws were often also obtained in these situations. In the context of a discussion concerning the measurement of sensation, the difference of forms between [3] and the Power law was deemed important. While not much mathematical theorizing was involved in any particular application of these ideas, a real challenge was offered by the need to construct a comprehensive theory linking all important aspects of

psychophysical methods and data. The most ambitious effort in this direction is due to Krantz (1972). For a slightly different approach to direct scaling, see Anderson (1981).

Functional Equation Methods

Because the data from psychophysical experiments are typically noisy, the theoretician may be reluctant to make specific assumptions regarding the form of some functions entering in the equations of a model. An example of such a model is [1], in which the functions u and F are not specified a priori. In such cases, the equations themselves may sometimes specify the functions implicitly. For instance, if we assume that both Weber's law and [1] hold, then Fechner's law must also hold, that is, the function u must be logarithmic, as in [3]. Many more difficult cases have been analyzed (see Aczel et al., 2000; for the application of functional equation methods in the behavioral sciences).

Signal Detection Theory

Response strategies are often available to a subject in a psychophysical experiment. Consider a situation in which the subject must detect a low intensity stimulus presented over a background noise. On some trials, just the background noise is presented. The subject may have a bias to respond 'yes' on some trials even though no clear detection occurred. This phenomenon prevents a straightforward analysis of the data because some successful 'yes' responses may be due to lucky guesses. A number of 'signal detection' theories have been designed for parsing out the subject's response strategy from the data. The key idea is to manipulate the subject's strategy by systematically varying the *payoff matrix*, that is, the system of rewards and penalties given to the subject for his or her responses. These fall in four categories: correct detection or 'hit'; correct rejection; incorrect detection or 'false alarm'; and incorrect rejection or 'miss.' An example of a payoff matrix is displayed in **Table 1**, in which the subject collects four monetary units in the case of a correct detection and loses one such unit in the case of a false alarm.

For any payoff matrix θ, we denote by $p_s(\theta)$ and $p_n(\theta)$ the probabilities of a correct detection and of a false alarm, respectively. Varying the payoff matrix θ over conditions yields estimates of points $(p_s(\theta), p_s(\theta))$ in the unit square. It is assumed that these points lie on a receiver-operator-characteristic (ROC) curve representing the graph of some ROC function $\rho : p_n(\theta) \mapsto p_s(\theta)$. The function ρ is typically assumed to be continuous and strictly increasing. The basic notion is that the subject's strategy varies along the ROC curves, while the discriminating ability varies across these curves. The following basic random variable model illustrates this interpretation.

Table 1 An example of payoff matrix. The subject collects four monetary units in the case of a correct detection (or hit)

		Responses	
		Yes	*No*
Stimulus	Yes	4 (Hit)	−2 (Miss)
	No	−1 (False alarm)	3 (Correct rejection)

Suppose that to each stimulus s is attached a random variable $\mathbf{U}_s$ representing the effect of the stimulus on the subject sensory system. Similarly, let $\mathbf{U}_n$ be a random variable representing the effect of the noise on that system. The random variables $\mathbf{U}_s$ and $\mathbf{U}_n$ are assumed to be independent. We also suppose that the subject responds 'yes' whenever some threshold λ_θ, (depending on the payoff matrix θ), is exceeded. We obtain the two equations

$$p_s(\theta) = \mathbb{P}(\mathbf{U}_s > \lambda_\theta), \quad p_n(\theta) = \mathbb{P}(\mathbf{U}_n > \lambda_\theta). \qquad [7]$$

The combined effects of detection ability and strategy on the subject's performance can be disentangled in this model, however. Under some general continuity and monotonicity conditions and because $\mathbf{U}_s$ and $\mathbf{U}_n$ are independent, we get

$$p(\mathbf{U}_s > \mathbf{U}_n) = \int_{-\infty}^{\infty} \mathbb{P}(\mathbf{U}_s > \lambda)\mathrm{d}\mathbb{P}(\mathbf{U}_n \leq \lambda) = \int_0^1 \rho(p)\mathrm{d}p, \quad [8]$$

with p the ROC function and after changing variable from λ to $p_n(\lambda) = p$. Thus, for a fixed pair (s, n), the area under the ROC curve, which does not depend upon the subject's strategy, is a measure of the probability that $\mathbf{U}_s$ exceeds $\mathbf{U}_n$. Note that [8] remains true under any arbitrary continuous strictly increasing transformation of the random variables. For practical reasons, specific hypotheses are often made on the distributions of these random variables, which are (in most cases) assumed to be Gaussian, with expectations $\mu_s = E(\mathbf{U}_s)$ and $\mu_n = E(\mathbf{U}_n)$, and a common variance equal to 1. Replotting the ROC curves in (standard) normal–normal coordinates, we see that each replotted ROC curve is a straight line with a slope equal to 1 and an intercept equal to $\mu_s - \mu_n$.

Obviously, this model is closely related to Thurstone's Law of Comparative Judgments. Using derivations similar to those leading to [4] and [5] and defining $d'(s,n) = \mu_s - \mu_n$ we obtain $\mathbb{P}(\mathbf{U}_s > \mathbf{U}_n) = \Phi(d'(s,n)/\sqrt{2})$, an equation linking the basic signal detectability index d' and the area under the ROC curve. The index d' has become a standard tool not only in sensory psychology but also in other fields where the paradigm is suitable and the subject's guessing strategy is of concern. Multidimensional versions of this Gaussian signal detection model have been developed. Various other models have also been considered for such data, involving either different assumptions on the distributions of the random variables $\mathbf{U}_s$ and $\mathbf{U}_n$, or even completely different models, such as 'threshold' models (Krantz, 1969). Presentations of this topic can be found in Green and Swets (1974) and MacMillan and Creelman (2004).

Mathematical models for 'multidimensional' psychophysics were also developed. One approach takes the guise of 'geometric representations of perceptual phenomena,' which is the title of a seminal volume on the topic (Luce et al., 1995; see, in particular Indow, 1995). Another approach emphasizes psychological dissimilarity as the foundational concept (Dzhafarov, 2011).

Measurement and Choice

Because they were preoccupied with the scientific bases of their discipline, a number of mathematical psychologists have

devoted considerable efforts to the elucidation of the foundation of measurement theory, that is, the set of principles governing the use of numbers in the statement and discussion of scientific facts and theories. An account of the results can be found in the three volumes of *Foundation of Measurement* (Krantz et al., 1971; Luce et al., 1990; Suppes et al., 1989).

The literature on choice theory is extensive. Contributors come from diverse fields including mathematical psychology, but also microeconomics, political science, and business, for example, the latter two concerned with the study of voter or consumer choice. Early on, the literature was dominated by Thurstone's Law of Comparative Judgments, which still remains influential. Many other situations and models have been analyzed, however, and we only give a few pointers here. A generalization of Thurstone model is obtained by dropping the assumption of normality of the random variables $\mathbf{U}_x$ and $\mathbf{U}_y$ in the last part of [4]. Despite many attempts, the problem of characterizing this model in terms of conditions on the binary choice probabilities, posed by Block and Marschak (1960), is still unsolved. In other words, we do not know which set of necessary and sufficient conditions on the choice probabilities $P(x, y)$ guarantee the existence of the random variables $\mathbf{U}_x$, $\mathbf{U}_y$ satisfying the first part of [4] for all x and y in the choice set. A number of partial results have been obtained, however.

In the *multiple choice paradigm*, the subject is presented with a subset Y of a basic finite set $\mathscr{X}$ of objects and is required to select one of the objects in Y. We denote by $P(x; Y)$ the probability of selecting x in Y. By abuse of notation, we also write $P(X;Y) = \sum_{x \in X} P(x;Y)$. Suppose that $P > 0$. The *Choice Axiom*, proposed by Luce (1959), states that, for all $Z \subseteq Y \subseteq W \subseteq \mathscr{X}$, we have

$$P(Z;Y)P(Y;W) = P(Z;W). \qquad [9]$$

Defining the function $v: x \mapsto P(x; \mathscr{X})$, [9] yields immediately $P(x;Y) = v(x)[\sum_{y \in Y} v(y)]^{-1}$, for all $Y \subseteq \mathscr{X}$ and $x \in Y$. This model plays an important role in the literature. In the binary case, it has an interpretation in terms of random variables as in the Thurstone model, but these random variables, rather than being Gaussian, have a negative exponential distribution.

In the general case of such a random variable model for the multiple choice paradigm, we simply suppose that to each x in $\mathscr{X}$ is attached a random variable $\mathbf{U}_x$ such that, for all subsets X of $\mathscr{X}$ and all x in X, we have

$$P(x;X) = \mathbb{P}\left(\mathbf{U}_x = \max\{\mathbf{U}_y | y \in X\}\right). \qquad [10]$$

The general characterization problem for this model has been solved by Falmagne (1978) who states necessary and sufficient conditions for the existence of the random variables satisfying [10]. His article also contains a uniqueness result. As in the binary case, specific assumptions can be made on the distributions of these random variables.

Other models, based on different principles, have also been proposed for the multiple choice paradigm. For example, in the *elimination by aspects* model, due to Tversky (1972), a subject's choice of some object x in a set X is regarded as resulting from an implicit Markovian-type process gradually narrowing down the acceptable possibilities. For reviews of probabilistic choice models see Luce and Suppes (1965) or Suppes et al. (1989). A sample of some of the results can be found in Marley (1997).

Response Time Models

The time or latency of a response has been used as a behavioral index of the sensory or mental processes involved in the task since the inception of experimental psychology in the nineteenth century. Many mathematical models are based on Donders's idea that the observed response time is a sum of a number of unobservable components including at least a sensory, a decision, and a motor response part (Donders, 1868/1969). These models make various assumptions on the distributions of the component times, which are often taken to be independent. McGill (1963), for instance, assumes that the component times are all distributed exponentially and independently, with possibly different parameters, so that their sum is distributed as a general gamma random variable.

Another category of models is grounded on the assumption that the observed response results from an unobservable accumulation of evidence with absorbing boundaries. These models are known as sequential sampling models (Busemeyer and Rapoport, 1988; Laming, 1968; Link and Heath, 1975; Ratcliff, 1978; Vickers, 1979), and are based on sequential sampling methods from statistics, including the sequential probability ratio test (Wald and Wolfowitz, 1948). As psychological models, sequential sampling processes assume the latent accumulation of information or evidence from a stimulus, based on a series of samples. When the accumulated evidence reaches a boundary or threshold, the decision corresponding to that boundary is made, and the number of samples taken provides a measure of the time taken to make the decision. This means the models generate a joint distribution over both decisions and response times. There are also some theoretical accounts of confidence that can be related to the dynamics of sequential sampling processes, and so allow this third behavioral variable to be modeled (Vickers, 1979; Pleskac and Busemeyer, 2010). In some reaction time situations, the successive stimuli follow each other in a fast-paced sequence. In such cases, prominent sequential effects appear. Markovian models explaining such sequential effect have been developed (Falmagne, 1965; Falmagne et al., 1975).

Within the general sequential sampling framework, there are many models and model classes making different assumptions about the way evidence is accumulated, and the form of the boundaries. Random-walk or drift diffusion models (Ratcliff, 1978; Ratcliff and McKoon, 2008) assume a single tally is maintained; race or accumulator models (Smith and Vickers, 1988; Vickers, 1970) maintain separate tallies for each alternative decision; and ballistic models (Brown and Heathcote, 2008) also maintain separate tallies but without stochastic variability. In most models, the sampling process that generates evidence from a stimulus is assumed to be homogeneous, and boundaries are also assumed to be constant throughout the decision-making process. There are, however, some exceptions Smith (2000), especially considering more general utilities incorporating deadlines or time pressure (Frazier and Yu, 2008), or considering mechanisms for the learning or self-regulation of the boundaries over trials (Busemeyer and Myung, 1992; Simen et al., 2006; Vickers, 1979).

Sequential sampling models were at first mostly applied to simple visual and perceptual decision-making phenomena, but have also found application in two other areas. One of these is in modeling higher-order cognitive processes such as categorization (Nosofsky and Palmeri, 1997) and judgment and preference phenomena, especially through decision field theory (Busemeyer and Townsend, 1993). The other is in combining behavioral and neuroscientific data relating to the time course of simple decisions (Gold and Shadlen, 2007; Smith and Ratcliff, 2004). There is recent work on hierarchical extensions of the model, to account for individual differences in subjects, differences between stimuli, and other sources of variation beyond the level of a single decision trial (Rouder et al., 2003; Vandekerckhove et al., in press).

Early work in the modeling of response times relied on analytic results, making the comparison of models to data, and the estimation of parameters from data tractable. Computational approaches have played a progressively more important role, but there continues to be important foundational mathematical development (Navarro and Fuss, 2009; Smith, 2000). Luce (1986) is a basic reference for the models and their applications, and Smith (2000) and Bogacz et al. (2006) provide reviews of many of the relevant mathematical and statistical results.

Other Topics

From these four traditional areas, research in mathematical psychology has grown to include a wide variety of subjects. Current research includes many aspects of perception, cognition, memory, decision making, and more generally information processing (cf Dosher and Sperling, 1998). In some cases, the models can be seen as more or less direct descendants of those proposed by earlier researchers in the field. The multinomial process tree models (Batchelder and Riefer, 1999), for instance, is in the spirit of the Markovian models of the learning theorists.

However, as with response time modeling, the advent of powerful computers also gave rise to different types of models for which the predictions could be obtained by simulation, rather than by mathematical derivation. Representative of this trend are the parallel distributed processing or connectionist models (Rumelhart and McClelland, 1986), scaling and clustering models of stimulus representation (Shepard, 1980; Navarro and Griffiths, 2008), and a wide range of cognitive process models, including especially models of category learning (Ashby and Maddox, 2005; Kruschke, 2008; Nosofsky, 1992) and memory (Clark and Gronlund, 1996; Norman et al., 2008). Despite the computational emphasis, there continue to be important mathematical results for some of these models (Myung et al., 2007; Navarro, 2005).

Most recently, Bayesian methods have had a rapid and widespread influence over the areas traditionally studied by mathematical psychology. There are at least three types of Bayesian influence on the field (Lee, 2011). One type involves applying Bayesian statistics for data analysis, and to compare and evaluate models (Pitt et al., 2002; Rouder et al., 2009; Kruschke, 2011). Another influence is as a framework for extending cognitive process model accounts of complicated behavioral data, allowing the incorporation of individual differences, stimulus variability, covariate information, and other hierarchical and latent mixture structure (Lee, 2008; Rouder et al., 2007). The third influence Bayesian methods have had is as a theoretical metaphor for the mind, to contrast with alternatives like the information processing or connectionist metaphors. The Bayesian view treats the mind as applying Bayesian inference to sparse and noisy data to learn about richly structured mental hypothesis spaces (Chater et al., 2006). This approach has risen quickly in prominence, and many Bayesian models have been developed across a wide range of phenomena, including especially generalization, concept learning, and inductive reasoning (Anderson, 1991; Kemp and Tenenbaum, 2008; Griffiths and Tenenbaum, 2009; Tenenbaum and Griffiths, 2001).

Finally, we mention *psychometrics*. The research in psychometrics concerns the elaboration of statistical models and techniques for the analysis of test results. As suggested by the term, the main objective is the assignment of one or more numbers to a subject for the purpose of measuring some mental or physical traits. In principle, such a topic could be regarded as part of our subject. For historical reasons, however, this line of work has remained separate from mathematical psychology. The research on knowledge spaces is an alternative to psychometrics. Instead of measuring a person's numerical aptitude in a subject, it uses stochastic algorithms to uncover the knowledge state of a person, which is the set of all concepts mastered by the person in that subject (Falmagne and Doignon, 2011).

The Journals, the Researchers, the Society

The research results in mathematical psychology are mostly published in specialized journals such as the *Journal of Mathematical Psychology*, *Mathematical Social Sciences*, *Psychometrika*, *Econometrica*, and *Mathematiques, Informatique et Sciences Humaines*. Some of the work also appears in mainstream publications: *Psychological Review* or *Psychonomic Bulletin & Review*. Early on, the research was typically produced by psychologists, and the work often had a strong experimental component. The last couple of decades other researchers became interested in the field, coming especially from economics, applied mathematics, and machine learning.

The Society for Mathematical Psychology (SMP) was founded in 1979. The society manages the *Journal of Mathematical Psychology* and organizes a yearly meeting gathering several hundred participants coming from all over the world. The European Mathematical Psychology Group (EMPG) is an informal association of about one hundred scientists meeting every summer in some European university. The first meeting was in 1971.

Abstract

The application of mathematics to certain problems within the field of psychology dates back to at least the seventeenth century. This article reviews some of these early applications, most of which either involve theories for experimental phenomena or statistical methods for measuring individual differences. These later applications led to the field of psychometrics in the 1930s; and the former led to the field of mathematical psychology in the 1950s, and both fields are active today. Early mathematical psychology was characterized by testable, formal theories in the areas of learning and memory, perception and psychophysics, choice and decision making, language and thinking, and measurement and scaling; and these areas still characterize the field today.

Introduction

The scientific use of mathematics to understand empirical observations has played a role in psychological theory at least as early as the seventeenth century; however, the term *mathematical psychology* does not simply refer to the scientific application of mathematics to psychology. Instead, mathematical psychology refers to a field of psychology established in the late 1950s by a small group of interdisciplinary scholars who were dissatisfied with the state of theory in experimental psychology at that time. These scholars had a vision for new ways to develop testable psychological theories that were informed by recent theoretical developments in modern mathematics and the information sciences. The field rapidly grew in the 1960s, and it is quite active today with contributions to all the areas of theoretical psychology.

The immediate groundwork for the development of mathematical psychology occurred with a flurry of papers and books in the 1950s that provided information-theoretic underpinnings for psychological theory in several research areas of psychology, notably: (1) learning and memory, (2) perception and psychophysics, (3) choice and decision making, (4) language and thinking, and (5) measurement and scaling. Many of these papers were reprinted in two volumes, titled *Readings in Mathematical Psychology* edited by Luce et al. (1963a, 1965a). At the same time, three volumes of the *Handbook of Mathematical Psychology* appeared, also edited by Luce et al. (1963b,c; 1965b), each with several long chapters representing new developments in the five research areas of the *Readings* volumes. In 1964, the *Journal of Mathematical Psychology* was started, and a year later *The British Journal of Statistical Psychology* changed its name to *The British Journal of Mathematical and Statistical Psychology*. Shortly thereafter, an annual conference on mathematical psychology was held in 1968 in the United States that eventually led to the formation of the Society for Mathematical Psychology. Also an annual conference on mathematical psychology started in Europe in 1971, and this led to the European Mathematical Psychology Group (EMPG). In addition, a growing number of universities offered graduate programs in mathematical psychology. With these developments, the establishment of mathematical psychology as an accepted field of psychology was complete (*see* Markov Decision Processes).

The remainder of this article will present some of the key mathematical developments in psychology that preceded the establishment of mathematical psychology as a formal field of psychology. A few of these developments occurred in the seventeenth and eighteenth centuries, before psychology became an accepted academic area of study; however, most occurred in the nineteenth century and in the early twentieth century. In the later part of the nineteenth century, psychology became recognized as a separate academic area of study in Germany and England. The main emphasis of psychology was quite different in these two countries, and this was reflected in their mathematical approaches. The German approach emphasized experimental psychology with a goal to understanding the common psychological processes that all humans share (normative psychology), where as the English focus was on measuring differences between humans on their psychological traits (differential psychology). In this time frame, the mathematical developments in psychology reflected these two approaches; however, the impetus that led to the creation of mathematical psychology was much more aligned with the experimental approach.

Mathematics and Psychology before the Nineteenth Century

Although the scientific use of mathematics before the nineteenth century was substantial, it was mostly seen in the areas of physics and chemistry. However, in that period a few important mathematical applications occurred in areas related to psychology, especially in the area of choice and decision making. Most modern theories of decision making assume that when making a choice between two or more probabilistic options, the decision maker considers and integrates in some way both the subjective probabilities of the options and their values (e.g., utilities) to the decision maker. The root of this idea goes back at least to Blaise Pascal (1623–62) in *Pensées*, a book constructed and published posthumously from his notes in 1670. In his notes, he

considers how a person facing a compulsory wager should choose between two incompatible, uncertain options when there are compelling arguments that either option may be the more likely. He argues that in such a case, the decision maker must consider the consequences of each option, or in other words, weigh the gains and losses. He goes on to apply his approach to a hypothetical wager on whether or not to believe that (a Christian) God exists. This situation has become known as Pascal's wager, and in his analysis of the consequences of each option, he sees a clear reason to select the option that God exists based on the supposed infinite positive value of eternal life compared with the minor negative value resulting from the embarrassment of being incorrect.

In the field of memory research, the scientist and inventor Robert Hooke (1635–1703) read a paper to the Royal Society of London in 1682 detailing a geometric model of human memory (Hintzman, 2003). The model appears to foreshadow many of the topics seen in the modern theories of memory; for example, explanations of encoding, retrieval, priming, and forgetting. In fact some of the aspects of Hooke's theory lead to mathematical laws; for example, Hintzman shows how one can derive a power function for forgetting based on the model, namely $s(l) = cl^{-2/3}$, where $s(l)$ is the memory strength after l time units since a memory was originally acquired and c is a constant depending on the nature of the memory. The shape of this forgetting function comes quite close to current studies of retention. Unfortunately, Hooke did not run any experiments, and apart from a few studies in perception and psychophysics in the eighteenth century discussed later, developers of mathematical theories in psychology did not conduct experiments to support their theories until the middle of the nineteenth century.

In the eighteenth century, additional grounding in decision making is attributable to Nicholas Bernoulli (1687–1759) and Daniel Bernoulli (1700–82). In 1713, Nicholas Bernoulli proposed what later became known as the St. Petersburg Paradox (Martin, 2011). The paradox concerns a lottery where you bet a sum of money and then flip a fair coin repeatedly until the first head appears. Your payoff for the bet depends on the number of flips needed to get the first head. In particular, if n is the number of flips until the first head appears, then you receive 2^{n-1} monitory units. Bernoulli shows that the expected value of this game is infinite, $\sum (½)^n 2^{n-1} = \infty$; therefore, he observed that one ought to be willing to pay any price to play the game. Of course it is obvious that a person would not pay a large amount to play, so this is where the paradox appears. A solution to the paradox was offered in 1738 by Daniel Bernoulli, who introduced the idea that a decision maker should consider utility rather than price, and this distinction has become an important component of modern decision-making theories. He pointed out that a given amount of money has different utilities depending on the needs of the decision maker, and that for all decision makers, the utility of money has decreasing marginal utility. He conjectured that the function relating price to utility was logarithmic, and that the initial wealth of the player must also be considered. Later others, including Laplace (1749–1827), proposed modifications to Daniel Bernoulli's analysis; however, the net effect of the St. Petersburg paradox was to provide a foundation for the critical variables in determining 'rational' decision-making behavior.

Considerations involving probability were also evident in the establishment of Bayesian reasoning in the eighteenth century. This development was due to the Reverend Thomas Bayes (1701–61), and to his important work, which was presented posthumously to the Royal Academy in 1763 in "An Essay Toward Solving a Problem in the Doctrine of Chances" (Bayes and Price, 1763). Although in the essay, he does not solve a problem directly connected with psychology, he did provide a new approach to statistical thinking that continues to have a great influence today in the statistical sciences.

Earlier work with probabilities had shown how to calculate the probability of an outcome given an explicit probability distribution; however, the key innovation in Bayes' work was to solve the so-called inverse probability problem, namely that given an outcome what can be said about the underlying probability that generated it. In particular, he showed a logically reasonable way to compare the probability of an event when one has no prior information versus when one has information consisting of the number of occurrences of the event out of n independent tries. Using his logic, he derived the beta posterior distribution for the uniform-binomial problem. In modern terms, this problem assumes that in the case that one knows nothing about the probability of the event, the prior probability p is uniformly distributed, $\pi(p) = 1$, $0 \leq p \leq 1$, and when one has knowledge of, say, s occurrences of the event out of n trials, then the posterior probability of p is given by:

$$g(p|s) = \frac{(n+2)!}{(s+1)(n-s+1)!} p^s (1-p)^{n-s}, \qquad [1]$$

with a posterior mean of $(s+1)/(n+2)$. Using Bayes' own reasoning, it is a small step to generalize eqn [1] to handle other probability distributions and types of evidence. Today, Bayesian statistics is a major area of statistical theory, and in mathematical psychology Bayesian ideas are increasingly influencing not only the structure of cognitive models but also the methods for estimating and evaluating them when confronted with data.

Other areas of psychology before the eighteenth century received very few applications of mathematics. Many historians of science attribute this lack to the influential philosopher, Immanuel Kant (1724–1804), whose writings are often interpreted as expressing the view that psychology cannot be a mathematical, experimental science (e.g., Hergenhahn, 2009). For example, in the *Metaphysical Foundations of Natural Science* of 1786, Kant points out that every natural science is essentially grounded in mathematics, and he goes on to argue that mathematics cannot be applied to the phenomenon of the internal senses. In an interesting essay, Sturm (2006) argues that Kant meant his remarks only to reflect the view that a science of psychology cannot be grounded on data provided by introspective (self) reports. Sturm goes on to show that in the period of Kant's writing, there were a number of ongoing experimental studies in the areas of perception and psychophysics, some known to Kant.

Examples were studies of visual acuity as a function of distance from a light source, brightness and color discrimination, and the durations of the after effects of visual, auditory, and tactile sensory experiences; and some of these studies included mathematical relationships between variables.

Mathematics and Psychology in the Nineteenth Century

Psychology achieved status as a separate academic field in the late nineteenth century after many experimental and theoretical developments. The transformation of psychology into a recognized university subject was due to research developments mostly in Germany and England. These developments led to quite different ways of using mathematics in psychological theory. In particular, the German approach emphasized the experimental method, where behavior is observed as a function of stimulus conditions manipulated by an experimenter. The primary goal of the experimental method is to develop theoretical laws of cognition that apply to all humans. On the other hand, the English approach emphasized how humans differ, and because these differences are due to both the genetic makeup and the environmental experiences of the individual, the experimental method is not of much use. Instead, the English approach involved developing and applying correlational methods to measure individual differences in psychological traits such as intelligence, attitudes, or personality traits. Cronbach (1957) has a nice discussion of the differences between the experimental and correlational approaches to psychological theory, and the next two sections discuss mathematical applications characteristic of these two approaches in the nineteenth century.

Mathematical Developments in German Psychology

In the case of Germany, most historians select Wilhelm Wundt (1832–1920) and the establishment of his experimental psychology laboratory at Leipzig, Germany in 1879 as the start of academic psychology in Germany (e.g., Hergenhahn, 2009). Before Wundt's laboratory was started, the German tradition was underway in the 1800s with major work in neural and sensory processes, psychophysics, attention, and choice response time. This work provided the main underpinnings of what was to become the field of experimental psychology. The early mathematical developments in German psychology were mostly in the areas of sensory processes and psychophysics, areas that enjoyed a connection to physiology and physics; however, mathematical developments in other more cognitive areas such as memory and choice reaction time occurred later in the century.

The area of psychophysics concerns the relationship between physical stimuli and the sensations that they create. The groundwork for psychophysics was established by the physiologist, Ernst Weber (1795–1878), who created the first experimentally validated mathematical law of the mind. Based on extensive experimental studies across a wide range of stimulus modalities, Weber noted that the smallest detectable increase in the intensity of a physical stimulus depends on its magnitude. This work led him to formulate the famous Weber's law, namely that the additional physical intensity needed to perceive a noticeable increase in sensation is directly proportional to the physical intensity, that is:

$$\Delta I = kI, \qquad [2]$$

where ΔI is the just noticeable increment in stimulus intensity I, and k is a constant that depends on the sensory modality. Now we know that Weber's law only holds strictly for a limited range of physical intensities, but the fact that it holds across a variety of modalities makes it an important theoretical milestone.

Gustav Fechner (1801–87), a physicist and mathematician, contributed many mathematical ideas in psychological theory connecting physical properties of stimuli to the sensations and perceptions they create. Much of this work was published in a two-volume work, *Elemente der Psychophysik* (*Elements of Psychophysics*). His most notable contribution was that he utilized Weber's law along with other mathematical assumptions to create his famous psychophysical law:

$$S = k \log I, \qquad [3]$$

namely that the perceived magnitude of a sensation S is functionally related to the logarithm of the corresponding physical intensity I that produced it. Fechner's work led to the creation of a large research field of psychology known as psychophysics, and many additional mathematical developments in this area followed on his ground-breaking work (*see* Markov Decision Processes and Psychophysical Theory and Laws, History of for details on Weber's and Fechner's contributions).

Like Fechner, Hermann von Helmholtz (1821–94) was another physicist and mathematician who made major contributions to experimental psychology. Among his many accomplishments outside of physics was his development of the resonance theory of hearing and the Young–Helmholtz theory of color vision. Both of these theories were invested in explaining how the human perceiver could detect a huge range of sound frequencies or colors with many fewer types of neurons. Also very important was his experimental work discovering that the speed of neural conduction was about ten times slower than the speed of sound, and is therefore capable of measurement.

Capitalizing on Helmholtz's discovery about the measurable rate of neural conduction, Franciscus Cornelius Donders (1818–89) devised an experimental approach along with a mathematical model to measure the amount of time that the mind needs to carry out elementary operations like perceiving a simple stimulus, discriminating between two simple stimuli, and making a simple choice. His mathematical ideas led to the so-called subtraction method. The essence of this method involves setting up two experimental conditions involving speeded responses, where one task is identical to the other except that it involves an additional elementary mental act. Then Donders' logic is to subtract the response time it takes to perform the simpler task from the response time to perform the more complex task, and the difference is then inferred to be the time that the mind needs to perform the additional act. Although the accuracy of his early measurements was not great, he is credited with

starting the area of mental chronometry, which is one of the main ways that experimental psychologists learn about mental information-processing architecture.

While most of the applications of mathematics in psychology in the German tradition were in the areas of sensation and perception, there were a few mathematical developments in the more cognitive areas of the mind as well. The most noted example was due to Johann Friedrich Herbart (1776–1841). Herbart developed an extensive mathematical system for understanding mental activity in terms of the interplay of combinations of ideas competing with each other to reach consciousness. The system was based on deterministic, mechanical laws, and at least some implications of his theory had the potential to be tested by experiment. Unfortunately, Herbart, who was a strong advocate of Kant's philosophy, interpreted Kant's writing about psychology as indicating that experimental psychology was impossible (see the previous section), and so unfortunately Herbart never tried to conduct experiments to test his theory (e.g., Boudewijnse et al., 1999).

Mathematical theories of mental activity that were connected to experimentation occurred much later in the nineteenth century. For example, Hermann Ebbinghaus (1850–1909) was the first psychologist to conduct rigorous experimental studies of memory. Ebbinghaus conducted numerous serial list-learning experiments on himself that verified some of the philosophical theories of memory association that trace back to Aristotle. Among his mathematical formulations is his famous exponential decay curve for forgetting in long-term memory. In fact, Ebbinghaus attributed his reading of Fechner's *Elemente der Psychophysik* with the ideas that led him to formulate his forgetting curve. Just as Fechner showed that increases in physical stimulus intensity exhibit decreasing marginal returns on sensation, Ebbinghaus showed that increases in time since study exhibit decreasing amounts of marginal forgetting.

Mathematical Developments in English Psychology

The English tradition in psychology can be traced to the work of Charles Darwin (1809–82) and especially research that followed in the spirit of his work. Darwin's theory of evolution was grounded on several principles, not the least of which was the fact that individuals differ in their physical traits. It was the work of Darwin's cousin, Sir Francis Galton (1822–1911), that set the stage for the emergence of English psychology. Galton's psychological concerns were mostly centered on ways to measure individual differences in a variety of personality and cognitive traits. Galton's interests in individual differences led him to establish a laboratory in 1884 where he studied differences in both physical and psychological traits in over 9000 individuals. The mathematical developments that came out of the English approach to psychology all involved the development of statistical theory. In fact, Galton is perhaps the principle figure behind the fact that England became a center for the development of statistical theory in the century after his birth (Stigler, 1986).

Galton was a pioneer in introducing the bivariate normal distribution to model the relationship between two measurable traits from the same individual. In this work, he introduced the concept of regression to the mean, which refers to the phenomenon that if an observation of a variable is extreme on its first measurement, then it is likely to be closer to the mean on its second measurement. Galton also laid the groundwork for the concept of the correlation coefficient as the measurement of the degree of statistical connection between two traits across a series of individuals. One impetus for this development was the so-called *Galton's problem*, which refers to the difficulty in drawing conclusions from cross-cultural measurements because they exhibit autocorrelation.

The final development of a measure of correlation was the Pearson product moment correlation coefficient, due to the statistician and mathematician Karl Pearson (1857–1936), who was a protégé of Galton. At the population level, the correlation between two random variables, X and Y, representing two traits of an individual is given by:

$$\rho(X,Y) = \frac{E\{[X-E(X)][Y-E(Y)]\}}{\sqrt{\mathrm{var}(X)\,\mathrm{var}(Y)}}, \qquad [4]$$

where $E(\bullet)$ is the expectation operator and $\mathrm{var}(X) = E[(X-E(X)]^2$.

The correlation coefficient at the level of a sample from a population became the central tool in the early studies of individual differences because of its many desirable properties such as its scale, $-1 \le \rho(X, Y) \le 1$, its role in providing best linear fits to scatter plots of individual trait variations, and the fact that ρ^2 is a measure of the variance in one trait 'explained' by the values of another trait.

Galton was quite interested in the nature of measurement error, an area of little interest except when regarded as a nuisance factor to experimental psychologists in the German tradition. He invented a model of measurement error known as Galton's box (quincunx) to illustrate the central limit theorem. Basically, the box is a physical device where a number of identical small balls can be dropped into a small hole at the top, and after falling down through a number of pins, they are collected into bins at the bottom of the box. Random error leads to an approximately normal distribution of the bin counts.

In 1873, Galton began an interest in the extinction of family names, and he proposed a stochastic branching process to examine this phenomenon. The process is defined by a sequence of random variables $\{X_n | n \ge 0\}$, where $X_0 \equiv 1$, and X_n is the population size of the nth generation. Galton sets up a recursion expressing X_n in terms of the offspring of members of the population on the previous generation, namely:

$$X_n = \sum_{j=1}^{X_{n-1}} Z_j, \qquad [5]$$

where $\{Z_j | j \ge 1\}$ is a family of independent and identically distributed random variables each of which represents the number of male offspring of a married man. Soon thereafter Henry Watson (1827–1903) formalized the process and provided a solution to the probability that the population will eventually die out, and this process, known as the Galton–Watson branching process, has been employed in a number of applications in the social and biological sciences.

Of particular interest to Galton and others in the English tradition was the study of intelligence. Galton's early interest

in intelligence led to a book in 1869, *Heredity Genius*, which attempted to study the distribution of genius in families. Galton's study of intelligence was thwarted by the lack of formal tests of intelligence; however, James McKeen Cattell (1860–1944), a research fellow under Galton, first began to develop measures of intelligence based on sensory acuity tests. By the end of the nineteenth century, Alfred Binet (1857–1911) and others had begun to develop tests of intelligence along with formal scoring procedures that were based more on cognitive than sensory abilities.

Roots of Mathematical Psychology in the Twentieth Century

By the start of the twentieth century, sophisticated statistical methods for the analysis of test data were developed. The key player in this work was Charles Spearman (1863–1945), an English psychologist who received a PhD in experimental psychology from Wundt, but later became fascinated by the writings of Galton, especially on intelligence. From this interest, Spearman (1904) invented a major statistical method used to study individual differences called factor analysis. He examined the pattern of correlation coefficients among assessments of academic achievement for a group of school children and found an orderly pattern that was discernible despite statistical error that became known as Spearman's law of tetrads. Suppose X_i, $i = 1, \ldots, n$ are random variables representing the scores of an individual on n tests. Then at the population level, the tetrad law states that all distinct sets of four tests, X_i, X_j, X_k, X_l:

$$\rho(X_i, X_j)\rho(X_k, X_l) = \rho(X_i, X_l)\rho(X_k, X_j). \qquad [6]$$

The tetrad law leads to a two-factor theory of intelligence for the scores on the battery of tests, namely that the score of an individual on a particular test depends on aspects unique to the particular test as well as a general intelligence factor that belongs to the individual test taker.

Early in the twentieth century, both the German and the English approaches to psychology were combined into academic psychology in the United States, which became the main center of psychological research in the world. In this period, mathematical applications in psychology were dominated by the English approach, and as a consequence they were mostly of a statistical character. One well-known drawback of factor analysis and other methods involving correlation is the inability to draw causal conclusions from patterns of correlations. Several approaches to this problem were proposed, such as the initial development of structural equations modeling (SEM) by the geneticist Sewall Wright (1889–1988), which appeared in Wright (1921). Subsequently, SEM was formalized into a standard approach to infer causal patterns from correlational data, and it is popular in psychology today. Another important statistical development was Sir Ronald Fisher's development of analysis of variance (ANOVA) in the 1920s. ANOVA remains one of the standard statistical tools used both in experimental and differential psychology. Another example is the further development of factor analysis by Leon Thurstone (1887–1955), who invented the common factor model. The approach in Thurstone (1935) allows one to explain observed test scores by multiple latent variables, which can be estimated by statistical methods based on the singular valued decomposition of the correlation matrix.

Work of this sort led to the formal field of *psychometrics*, and most mathematically sophisticated psychologists in this period were psychometricians. The Psychometrics Society started in 1935, and the flagship journal, *Psychometrika*, started a year later. As stated on the cover of the early issues of *Psychometrika*, the mission of the Society and its journal was "devoted to the development of psychology as a quantitative rational science" (Green, 1986). Nevertheless, despite the inclusiveness suggested by this statement, most of the publications in *Psychometrika* involved statistical methods in the spirit of the work initially begun in the English tradition by Galton and his followers.

Mathematical psychology as a formal field of psychology did not emerge as a development within psychometrics, and instead, as explained in the introduction to this article, it was begun by researchers seeking new mathematical theories for experimental phenomena in five main subareas of experimental psychology listed there. However, due to lack of a natural journal outlet, some of the early papers in mathematical psychology were published in *Psychometrika*. The remainder of this section will consist of five subsections that will briefly describe several of the key papers that came to form the central areas of research in mathematical psychology. For further discussion of these and related papers, other articles in this Encyclopedia can be consulted.

Mathematical Learning Theory

As the 1950s began, experimental psychology was dominated by behavioral learning theory, so it is not surprising that much of the early work in mathematical psychology concerned mathematical models of the learning process. A typical learning experiment involves an organism learning to select appropriate responses to experimentally presented stimuli over repeated trials. This experimental structure was a natural for stochastic modeling, and two influential approaches in this spirit were developed. One was due to the psychologist William K. Estes (1919–2011), which led to the development of stimulus sampling theory; and the other approach was due to a collaboration between a physicist, Robert R. Bush (1920–72), and a statistician, Frederick Mosteller (1916–2006), which led to linear operator models. The work in these two approaches was initiated by two seminal papers that appeared in *Psychological Review*: Estes (1950) and Bush and Mosteller (1951). Both of these papers showed how one could develop stochastic models that could successfully predict the detailed statistics of the learning process in simple situations. Very shortly after these two seminal publications, mathematical learning theory became a central topic in mathematical psychology (e.g., Bush and Estes, 1959).

Even though mathematical learning theory was one of the immediate progenitors of mathematical psychology, there were intellectual predecessors to this work in the 1900s. For one, Thurstone (1930) proposed a mathematical theory of the learning curve that is remarkably modern in its foundations. Basically Thurstone regarded a learning task as consisting of

a collection of acts, some that succeed and some that fail. He develops the mathematics of a formal urn-sampling scheme, where acts are drawn at random. If an act that fails is drawn, it is eliminated with a certain probability, and so learning consists of increasing the proportion of successful acts, which is in turn a function of the model's parameters. In addition, Thurstone has equations that lead to a decrease in recurrence of unsuccessful acts and an increase in successful acts. However, unlike the work of Estes and Bush and Mosteller, Thurstone did not validate his theory with extensive statistical analysis of learning data.

Another predecessor to mathematical learning theory in the 1950s was the work of the major learning theorist, Clark Hull (1884–1952). Hull's (1943) book is full of postulates and theorems that predict the quantitative details of an organism's behavior in a learning situation. Despite the liberal use of mathematical notation in this work, it has been generally accepted that it was a failure in that it did not provide any solid measurement scales for implicit variables like drive and incentive. Indeed, it was partly as a reaction to the failed goals of Hull's work, that the work of Estes and Bush and Mosteller was initiated.

Perception and Psychophysics

In the area of psychophysics, a major advance took place in the 1950s that became a central aspect of mathematical psychology. This advance involved new mathematical models for how human observers detect signals imbedded in noise. These models were developed from ideas already worked out in the field of electrical engineering known as signal processing. The transfer of this knowledge to psychophysics occurred in two seminal papers: Tanner and Swets (1954) and Swets et al. (1955). Consider the special case of auditory signal detection. The authors discussed a simple auditory signal detection experiment in which a sample of random, 'white noise' is delivered to the subject on each of a series of discrete trials, sometimes along with a signal consisting of a pure tone of a fixed frequency. The subject's task is to respond 'yes' or 'no' on each trial depending on whether or not they think the signal tone was present. Such responses can be classified into 'hits,' correctly detecting a signal, 'false alarms,' incorrectly calling a noise trial a signal trial, 'misses,' failing to detect a signal, and 'correct rejections,' not detecting a signal on a noise trial. In the earlier work in signal processing, optimal statistical detectors had been derived based on the fact that in the physical setup, the statistical properties of signal and noise trials could be represented by probability distributions. However, in the psychophysical setting, the impact of the stimuli on the brain precluded the derivation of an optimal human detector. Nevertheless, human performance in the signal detection task could be compared with the optimal detector in a way to shed light on the underlying psychophysical processes in simple auditory perception.

Soon thereafter, signal detection theory began to be used in other, nonsensory areas of cognition. For example, Egan (1958) in an unpublished but highly cited technical report noticed that the structure of the signal detection task is identical to a number of other detection tasks that do not involve mathematically describable stimuli – for example, simple recognition memory – where the subject must detect whether or not a test item was on a previous study list. Egan's insight triggered a cottage industry in new cognitive models for recognition memory, and this continues to the present time as perhaps the largest area of formal modeling in mathematical psychology.

Choice and Decision Making

Of central importance in the area of decision making was the publication of *Theory of Games and Economic Behavior* by Von Neumann and Morgenstern (1944). The scope of the theory includes not only social interactions that involve conflicts of interest but also all situations in which individuals or groups make choices among actions or strategies whose outcomes involve uncertainty and risk. Although the work was central to economic theory, it has provided the formal framework within which psychological theories of human decision theories have been developed. A little over a decade later, a related book on game theory appeared, *Games and Decisions: Introduction and Critical Survey* (1957) by R. Duncan Luce (1925–2012) and Howard Raiffa that contributed to attracting psychologists as well as economists to the subject.

Another influential book in establishing mathematical psychology in the area of choice and decision making was *Individual Choice Behavior: A Theoretical Analysis* by Luce (1959). In it, Luce proposed the so-called choice axiom for probabilistic choice behavior, where a chooser must select one of the choice alternatives from a proffered choice set. One of the key ideas is to represent choice alternatives as members of a master set, $T = \{a_i | 1 \leq i \leq n\}$, and the axiom supposes that choice from different contexts (subsets of the master set) behaves like conditional probability behaves. In particular, if each alternative in a choice set has a positive probability of being chosen from any choice set that includes it, then the axiom states that:

$$\forall\ A \subseteq S \subseteq T,\ \ \mathbf{P}_T(A) = \mathbf{P}_S(A)\mathbf{P}_T(S), \qquad [7]$$

where, for example, $\mathbf{P}_S(A)$ is the probability that if a choice set S is presented the chosen alternative is in the set A. The axiom has many implications; for example, it is possible to show from eqn [7] that there exists a function $v(a)$ from the master choice set into the positive reals such that:

$$\forall\ a \in S \subseteq T,\ \ \mathbf{P}_S(\{a\}) = \frac{v(a)}{\sum_{b \in S} v(b)}. \qquad [8]$$

Equation [8] became known as Luce's ratio rule seen later in many applications in cognitive models of memory and categorization.

In addition, when the positive probability condition is removed from the choice axiom, allowing some alternatives to have zero probability of being chosen in certain contexts, there are many more theoretical results that can be derived from the choice axiom. In fact the book shows applications of the choice axiom in learning theory, information theory, psychophysics, and utility scaling. Of course the axiom as expressed in eqn [7] is too simple to handle complex choice situations

involving similarities among choice objects as well as context effects; however, it illustrates one of the central approaches in early mathematical psychology, namely, to capture in detail simple, nontrivial situations as a building block for more complex systems.

In the case that only choice sets of cardinality two are presented to the subject, one has what is called a paired-comparison experiment, and eqn [8] reduces to a logistic statistical model developed earlier by the statisticians Bradley and Terry (1952), and it is now called the BTL model. Even earlier than that, Thurstone (1927) developed a paired-comparison model based on Gaussian rather than logistic distributions. The BTL and Thurstone paired-comparison models became the building blocks, respectively, of logit and probit analysis used in the social sciences, especially econometrics, to analyze binary response data. Another area involving choice that became important in mathematical psychology was the effort to explain the time it takes to make simple choices. Since the 1950s, mathematical psychologists have developed a number of mathematical models for predicting the response times to perform various simple choice tasks, such as deciding which of two objects is larger, which tone has just sounded, or whether or not a string of letters is a word. On the mathematical side, this work was facilitated by earlier work in stochastic processes, such as the identity for sums of random variables developed by Abraham Wald (1902–50) and the mathematical developments of Brownian motion diffusion processes by Norbert Weiner (1894–1964) (e.g., Feller, 1957). Mathematical psychologists have used these and other mathematical results to regard a simple choice between two objects to be an accumulation of evidence for each governed by a diffusion process. This work represents a culmination of the work discussed earlier by Helmholtz and Donders concerning the timing of nervous and mental events.

Language and Thinking

In the areas of language and thinking, major progress was made possible by developments in the information sciences, in particular the formal theory of computation known as automata theory as well as the early design of digital computers. In the case of language, Chomsky (1959) developed the first formal models of grammar, and tied the theory of grammars to the computational hierarchy in automata theory. In the area of thinking, Newell et al. (1959) first published a computer model of human problem solving that was developed in the decade to follow into a major computer simulation project by Newell and Simon called the *Human Problem Solver*. These two projects received a lot of coverage in the *Handbook of Mathematical Psychology* discussed in the introduction to this article, and there were initial hopes that these areas would become basic subareas of mathematical psychology. However, as future work in these areas continued, it turned out not to be closely associated with mathematical psychology as it developed after the 1960s.

Measurement and Scaling

As mentioned earlier, before the 1950s, the development of approaches to the measurement of psychological quantities was the province of psychometricians. This work emphasized the structure of measurement error and the development of high-power statistical methods that enabled a researcher to analyze error-prone response data and retrieve its underlying structure. However, little of the psychometric work concerned the structure of the psychological quantities being measured or the cognitive factors behind the generation of the response data. There were three important new theoretical approaches to measurement and scaling in the 1950s that became strongly associated with mathematical psychology. The first was to attempt to understand at a foundational level the relationship between the structure of data and the structure of numerical systems that represent the data. This area was initiated in psychology with Suppes (1951) and Scott and Suppes (1958). These early efforts approached the measurement problem by representing the empirical situation as a relational structure with axioms that jointly reflect the measurement operations at the empirical level. Suitable axioms then permit a homomorphism from the empirical relational structure into a suitable numerical relational structure, where justified computations can be carried out. Others soon joined this effort, and it led to the area known as foundations of measurement that became one of the main research areas in mathematical psychology (e.g., Krantz et al., 1971).

The second new theoretical advance in the areas of measurement and scaling was to construct formal cognitive models of the respondent in a measurement situation rather than statistical data processing algorithms. The leader in this work was Clyde H. Coombs (1912–88). One example is Coombs (1950), where he formalized the one-dimensional unfolding model for a situation where respondents rank order their preferences for a series of items. The idea is that both the items and the respondents are simultaneously scaled on a single dimension, and each respondent ranks the objects in order of increasing distance from the placement of the respondent. Unfolding theory was extended to multiple dimensions, and it has become an often-preferred scaling model in the social and behavioral sciences. Coombs early contributions to model-based scaling methodology gave rise to his major work in this area (Coombs, 1964). A third major breakthrough in measurement and scaling in the 1950s was the development of a new form of the psychophysical scaling function along with new methods of collecting psychophysical data. As mentioned earlier, a major advance in psychology was Fechner's derivation of the logarithmic psychophysical function from Weber's law and mathematical considerations in eqn [3]. Weber used psychophysical paradigms where a subject would decide which of two stimuli was perceived to be more intense. In a major theoretical advance, Stevens (1957) changed Weber's procedure and began to ask subjects to make direct numerical estimates of the magnitude of the perceived intensities of sensory stimuli, such as weights, loudness, and time duration. In many cases, Steven's data were fit closely by the so-called Steven's power law:

$$\Psi(I) = \alpha I^{\beta}, \qquad [9]$$

where I is a physical intensity and $\alpha > 0$, $\beta \in \mathrm{Re}$ are constants that depend both on the subject and the psychophysical continuum. Several mathematical psychologists, who sought

to discover the foundational assumptions behind the law, pursued Stevens' contribution to psychophysics later. In addition, Stevens' approach was developed into a measurement technique that led to wide use in many areas of the social and behavioral sciences.

Conclusion

This article has examined some of the history of how mathematics has been applied in psychology from the seventeenth century to the mid-1950s when mathematical psychology was developed into a formal field of psychology. There have been two main themes in this history, one characterized by mathematically based theories of psychological properties of humans in general, and the other characterized by statistically based methods of measuring individual differences in psychological traits. The first is exemplified by developments in German experimental psychology in the nineteenth century in areas such as choice response time, memory, perception, and psychophysics; and the second is due to developments at approximately the same time in English differential psychology in areas such as assessing individual differences in intelligence, attitudes, and personality traits. It is fair to say that the research areas of the field of mathematical psychology come mostly from the experimental approach, and the mathematical concepts that are used are usually drawn from mathematical developments in modern mathematics and information science, mostly developed in the first half of the twentieth century. The usual approach in early mathematical psychology was to develop simple, clear theoretical ideas that could handle empirical observations in simple experiments. These mathematical approaches allowed one to state their theory precisely with testable assumptions. This approach still characterizes the field today, and almost every area of theoretical psychology has by now been positively affected by the work of mathematical psychologists.

Abstract

This article first describes the nature of mathematics as an intellectual domain and how several general theoretical perspectives in educational psychology as well as mathematics-specific theories have influenced and still influence research on mathematics education. Subsequently, we review the current research-based views on (1) mathematical competence, (2) learning mathematics, and (3) teaching mathematics.

During the past decades mathematics education has evolved from a terrain operated on by various groups of scholars – psychologists, mathematicians, and educational scientists – with very different theoretical and methodological backgrounds, research goals, and with little or no mutual interaction in an interdisciplinary field of study in which not only the scholars with above-mentioned disciplinary backgrounds, but also historians, philosophers, sociologists, anthropologists, and, more recently, cognitive and educational neuroscientists, actively cooperate (De Corte and Verschaffel, 2006; Sriraman and English, 2010). Thus, to a considerable extent, the past decades have witnessed the emergence of research in mathematics education as a field of study in its own right, even as it maintains strong symbiotic links with other disciplines. Of these other disciplines, psychology and mathematics themselves remained, of course, preeminent, but, increasingly, an important role is being played by the other above-mentioned disciplines, reflecting the increasing recognition of the 'situatedness' of mathematical thinking and learning in social, cultural, and historical contexts (De Corte and Verschaffel, 2006) as well as its physical 'embodiment' (Lakoff and Núñez, 1997).

In the first section we briefly reflect on mathematics as an intellectual domain. Thereafter, we introduce several general as well as domain-specific theoretical perspectives that have historically shaped today's thinking about mathematics education. In the main body of the article, we review the current research-based view on three major aspects of mathematics education: (1) mathematical competence, (2) learning mathematics, and (3) teaching mathematics.

For a more complete overview of these topics, we refer to the following recent volumes in which the vast body of theoretical reflection and empirical research in mathematics education has been extensively reviewed: *Mathematics Education as a Research Domain* (Sierpinska and Kilpatrick, 1999), *Handbook of Research on the Psychology of Mathematics Education* (Gutteriez and Boero, 2006), *Second Handbook of Research on Mathematics Teaching and Learning* (Lester, 2007), and *Theories of Mathematics Education* (Sriraman and English, 2010).

Mathematics

When people refer to mathematics, they mostly refer to formal academic or professional mathematics – that is, the scholarly study of quantity, space, and structure, by seeking out patterns, formulating new conjectures, and establishing truth by rigorous deduction from appropriately chosen axioms and definitions, or the simplified version of it they learnt at school. But mathematics also involves the more informal kinds of human practices related to number, space, and patterns that are present in human activities like counting, locating, measuring, designing, playing, and explaining.

The answer to the question 'What is mathematics?' has changed throughout history and will continue to change. Very broadly, the answer during the twentieth century has evolved from 'the science of number and space' to a more abstract characterization such as 'the science of patterns.' However, others would give more weight to 'problem solving' or the 'modeling' aspects of the real world, and the quest for a single phrase that could encapsulate an intellectual enterprise with so many facets seems pointless. Two other elements of development in the conception of what mathematics essentially is, are: (1) the shift away from the view of mathematics as the epitome of 'certain knowledge' and toward a conceptualization as an activity grounded in human practices and (2) the increasing use of computers in mathematical research, which has resulted in a greater emphasis on mathematics as an experimental science and forced reconsideration of the nature of proof.

Researchers attempting to describe what makes mathematics significantly different from other intellectual or scientific domains point to its 'dual nature': mathematics as a descriptor of a perceived reality, but at the same time, as an autonomous abstract construction. This duality is acknowledged in the distinction between applied mathematics (the branch of mathematics concerned with application of mathematical knowledge to other fields such as natural science, engineering, medicine, and social sciences) and pure mathematics (mathematics for its own sake, without having any application in mind). These two different and complementary aspects of mathematics, the practical and theoretical, have earned the subject a place at the center of education throughout history. Some other typical features of mathematics are: its hierarchically structured development on both the cultural and individual planes, and the intrinsic inaccessibility of mathematical (thinking) objects, implying that their conceptual acquisition necessarily passes through the acquisition of one or more semiotic representations.

Even though there is little doubt that mathematics is a unique and integral intellectual domain, it is also possible to look at it as an aggregation of subdomains that differ in terms of their most characteristic methods, styles of thinking, and forms of representation, and which therefore may need different 'local' theories of expertise, learning, instruction, and assessment. These subdomains are typically represented in leading handbooks on mathematics education as edited by Gutteriez and Boero (2006) and Lester (2007), which include chapters on arithmetic, algebra, geometry, and statistics and probability.

Theoretical Views on Mathematics Education

One way to categorize the theoretical orientations of the research and analyses of the nature of mathematical cognition, how it is learnt, and how this learning can be optimally enhanced, is by referring to the broad paradigmatic traditions within psychology and education in general: the behaviorist/empiricist, the cognitive/rationalist, and the situative/pragmatist–sociohistoric tradition (Greeno et al., 1996). These general theories have largely influenced, and continue to influence, the research field of mathematics education.

The behaviorist/empiricist tradition includes associationism, behaviorism, and connectionism. According to this view, mathematical knowledge and skills are the result of an accumulation of acquired associations and skills. A classic example of this tradition is Thorndike, who applied his associationist view on learning (as differential strengthening of associations by reinforcement) to the learning of arithmetic. Although this tradition plays a minor role in contemporary research, its ideas still permeate into current instructional practices: for example, in drill-and-practice approaches. Conceptions of mathematics as providing correct answers to well-defined mathematics tasks, of learning mathematics as incremental (with errors to be avoided or immediately stamped out), and of mathematics teaching as the reinforcement of mathematically correct responses, remain prevalent in many current instructional practices and, as such, represent the legacy of this first tradition.

The cognitive/rationalist perspective involves research traditions such as Gestalt psychology, symbolic information processing, and constructivism. These traditions conceive mathematical knowledge as universal mental entities located in individual learners, such as cognitive schemes and procedural rules, and define learning mathematics as changes in these universal mental schemes and rules. Typical representatives of this tradition are Piaget, who theorized mathematical development in terms of the stepwise acquisition of increasingly complex logicomathematical structures; Wertheimer, who emphasized the insightful detection and exploitation of structure in mathematical thinking and learning; and information-processing theorists such as Simon, Anderson, and Siegler, who performed fine-grained analyses of the cognitive structures and processes involved in the acquisition and use of key mathematical concepts and skills. This perspective has also had a clear impact on the practice of mathematics education: performing detailed analyses of the concepts and skills needed to perform certain mathematical tasks, looking at mathematical learning processes rather than learning outcomes, paying ample attention to the role of prior knowledge, valuing conceptual understanding, and problem solving besides procedural fluency are reminiscent of this second perspective.

The situative/pragmatist–sociohistoric perspective entails traditions such as ethnography, anthropology, and situation theory. This third framework embraces all those theories that view mathematics learning as a reorganization of activity that accompanies the integration of an individual learner within a 'community of practice.' Having its origins in Vygotsky's work, this third tradition emerged strongly in the late 1980s in reaction to the then dominant cognitive view of mathematics learning as a highly individual and purely mentalistic process of knowledge and skill acquisition occurring in the learner. In contrast to this cognitivist view, the situated perspective stresses that mathematics learning is enacted essentially in interaction with social and cultural contexts and artifacts, and especially through participation in cultural activities and contexts. Whereas in the cognitivist view, mathematics is seen as a universal knowledge system, the situative/pragmatist–sociohistoric perspective assumes that mathematics differs according to the setting in which it has been developed and in which it is practiced. The influence of this perspective on mathematics education is reflected in attempts to implement elements of successful out-of-school learning settings into school mathematics, and increased attention to the sociocultural and affective side of mathematics learning and teaching.

However, research in mathematics education of the past decades is not merely, not even primarily, theoretically framed in terms of the three above-mentioned general traditions. Of the many theories that have been developed over the past decades and are being used within the field of mathematics education, the dominant ones are 'home-grown theories.' Such theories put the specificity and integrity of the domain at the center, with no hesitation, whatsoever, to borrow ideas and techniques from other disciplines. But they have little or no interest in the possible relevance of the theory outside the field of mathematics education. Therefore, since its emergence as a field in its own right, mathematics education has witnessed many such home-grown theories of mathematical cognition, learning, and teaching, such as Brownell's (1945) theory of what he called 'meaningful mathematics,' emphasizing the understanding of mathematical relationships and the ability to think quantitatively, Skemp's (1979) theoretical distinction between 'instrumental' and 'relational understanding' of mathematics, Van Hiele's (1986) theory of how children learn geometry, Pólya's (1945) analysis of the role of heuristic processes in mathematical problem solving, Freudenthal's (1983) view on mathematics (education) as a human activity, which formed the basis of the Dutch model of 'realistic mathematics education,' and Fischbein's (1987) theory of the intuitive sources of mathematical thinking – to mention just few 'giants' of the history of research in mathematics education. Although well versed in the theories and methods of psychology, most of them were quite critical of its limited application to the domain of mathematical cognition, learning, and teaching, and emphasized that (the psychology of) mathematics education had to develop its own questions, and theoretical and methodological perspectives (Verschaffel and Greer, 2013).

In the course of development, tensions and perspectival differences between mathematics educators on the one hand

and psychologists, educational scientists, and mathematicians on the other hand, have continued. The books edited by Sierpinska and Kilpatrick (1999) and Sriraman and English (2010), for instance, make clear that the field has far from settled into a phase of 'normal science' (in the Kuhnian sense). But rather it has entered a period of considerable complexity and diversity in theoretical perspectives, experimental methodologies, and reflections, not only on the fundamental questions of what mathematics is and how it can be learnt and taught, but also of the equally fundamental question what is mathematics (education) education *for*?

Mathematical Competence

While for a long time it was quite common to think of mathematical competence as the mastery of specific knowledge and skills, it is now generally agreed that it involves a broad set of competencies including (De Corte and Verschaffel, 2006):

- A well-organized and flexibly accessible domain-specific knowledge base involving facts, symbols, conventions, definitions, formulas, algorithms, concepts, and rules that constitute the contents of mathematics as a subject-matter field.
- Heuristic methods, that is, search strategies for problem solving that do not guarantee but significantly increase the probability of finding the correct solution because they induce a systematic approach to the task (e.g., thinking of an analogous problem, decomposing a problem into subgoals, and visualizing the problem using a diagram or a drawing).
- Metaknowledge, which involves knowledge about one's cognitive functioning (metacognitive knowledge, e.g., believing that one's cognitive potential can be developed and improved through learning and effort) and knowledge about one's motivation and emotions that can be used to deliberately improve volitional efficiency (e.g., becoming aware of one's fear or failure when confronted with a complex mathematical task or problem).
- Self-regulatory skills, which embrace skills relating to the self-regulation of one's cognitive processes (metacognitive skills or cognitive self-regulation; e.g., planning and monitoring one's problem-solving processes) and skills for regulating one's volitional processes/activities (metavolitional skills or volitional self-regulation; e.g., keeping up one's attention and motivation to solve a given problem).
- Positive beliefs about oneself in relation to mathematical learning and problem solving (self-efficacy beliefs), about the social context in which mathematical activities take place, and about mathematics and mathematical learning and problem solving.

This broad conception of mathematical competence is nicely reflected in the characterization of 'mathematical proficiency' in the report of the U.S. National Research Council (2001), *Adding it up*, wherein proficiency is defined in terms of five strongly interwoven strands, namely:

- conceptual understanding, comprehension of mathematical concepts, operations, and relations;
- procedural fluency, skill in carrying out procedures flexibly, accurately, efficiently, and appropriately;
- strategic competence, the ability to formulate, represent, and solve mathematical problems;
- adaptive reasoning, the capacity for logical thought reflection, explanation, and justification; and
- productive disposition, a habitual inclination to see mathematics as sensible, useful, and worthwhile discipline, coupled with a belief in diligence and one's efficacy.

It is certainly useful to distinguish these different categories of components, but it is also important to realize that in expert mathematical cognition they are applied integratively and interactively. Actually, research in mathematical subdomains, such as whole number arithmetic, algebra, geometry, and statistics, contains numerous illustrations of the importance and interdependency of these different strands of proficiency (see, e.g., Gutteriez and Boero, 2006; Lester, 2007).

Learning Mathematics

In line with the above broad conception of mathematical competence, it is now quite generally agreed that mathematics learning is not a one-dimensional phenomenon; as it proceeds, each strand of mathematical proficiency develops in interaction with the others. Moreover, research over the past decades has resulted in the view of mathematics learning as active and cumulative construction of mathematical proficiency – constrained by the structural and functional properties of the human cognitive architecture, and by the form of the human body more generally (i.e., embodied cognition), and situated in a given community of learners and a broader sociocultural context.

The view of learning as an active and constructive process is now the common ground among mathematics educators and is supported by substantial empirical evidence. Essentially, mathematical competence is seen as the result of the mindful and effortful involvement of the learner in the processes of knowledge and skill acquisition in interaction with the environment, rather than the result of direct information transmission. This involvement is well illustrated in children's invented idiosyncratic but accurate procedures for solving arithmetic problems in school as well as out-of-school contexts. For instance, some children seem to find out by themselves that subtraction problems of the type $82 - 78 = \ldots$ can be efficiently solved by a subtraction-by-addition strategy, whereby the result is found by determining how much should be added to the smaller number to arrive at the larger one. However, the constructive nature of learning is also expressed in a negative way in misconceptions and in defective or 'buggy' procedures that many learners acquire. Examples of misconceptions are: "multiplication always makes bigger whereas division always makes smaller" and "every number has a number immediately preceding and following it." Illustrations of defective procedures are in multidigit subtraction, subtracting in each column the smaller digit from the larger, and in addition of fractions, simply adding the nominators and the denominators, that many learners acquire.

The constructive nature of mathematics learning involves that it is also cumulative. Indeed, students build new

knowledge and skills on the basis of what they already know and can do. This pivotal role of prior knowledge can affect learning in both positive and negative ways. There is, for instance, ample evidence that children's thinking about number relies on certain core principles or presuppositions that are based on their experience with natural numbers. This facilitates some kinds of learning but inhibits others. For example, children's early understanding of natural number and its properties strongly supports their conception of multiplication as repeated addition (Fischbein, 1987). But at the same time it leads to the misconceptions, mentioned in the preceding paragraph, that multiplication always leads to a bigger result, or that every number has a number immediately preceding or following it (Vosniadou and Verschaffel, 2004). The view of learning as a constructive activity implies also its self-regulatory nature: learners have to assume control over their own learning, thinking, and problem-solving activities (De Corte et al., 2010).

Furthermore, mathematics learning is constrained by the human cognitive architecture and functioning, that is, the manner in which our cognitive structures are organized in memory and our information-processing system works. Most treatments of the human cognitive architecture use the sensory memory/working memory/long-term memory model as their base. It is generally accepted that the characteristics of working memory and long-term memory and their functional relations (e.g., the fact that, when processing novel information, working memory is very limited in duration and in capacity) determine the quantity and quality of what will actually be learnt. For instance, it is well known that low working memory is a barrier to the learning of both simple calculations and higher level problem solving. It has also been shown that children with mathematics disability have memory deficits that are directly responsible for their disability. These memory problems prevent them from memorizing and/or recalling arithmetic facts, which leads to difficulties executing calculation procedures, or create problems with the temporary storage of numbers in working memory, which is detrimental for doing complex mental arithmetic or problem solving.

It is also increasingly accepted that (mathematical) cognition is shaped by aspects of the body, such as the motor system, the perceptual system, and how the body is functioning in the environment. This theoretical perspective of 'embodied cognition,' which emphasizes that (mathematical) cognition is situated and made comprehensible by the shared biology and fundamental bodily experiences of human beings, entails a reconceptualization of cognition and mathematics itself, and may also have important consequences for mathematics education. According to Lakoff and Núñez (1997), abstract concepts, such as 'balancing' a system of simultaneous equations, are conceptual extensions of the image schemata involved in the bodily experience of 'balance.' As Lakoff and Núñez (1997: p. 30) state, "much of what is 'abstract' in mathematics (…) concerns coordination of meanings and sense making based on common image-schemata and forms of metaphorical thought. Abstract reasoning and cognition are thus genuine embodied processes." At a more basic level, various studies have pointed to finger counting as prime example of embodied cognition.

Finally, mathematics learning – and mathematics as such – are not only situated in a person's body, but also in the broader sociocultural environment, which means that it is enacted essentially within social and cultural contexts and in interaction with other people and artifacts, especially through participation in sociocultural activities and communities. Thus, mathematics educators have now broadly embraced the view that mathematics learning is not a purely solitaire and mental activity; rather thinking and learning processes are distributed over the individual learner, his/her partners in the environment, and available representational tools (e.g., abacus) and technological resources (e.g., computer and interactive whiteboard). The outcomes of a large series of ethno-mathematical studies of the informal calculation procedures, problem-solving strategies, and learning mechanisms of particular groups of adults involved in everyday cultural practices, such as tailoring, weaving, carpentry, navigating, grocery, packing, and cooking, has largely contributed to the popularity of this viewpoint. Although the situated nature of doing and learning mathematics has been documented especially well within such out-of-school contexts, it is obvious that this situatedness also applies to mathematics learning *in school*. For instance, the numerous examples of students' 'suspension of sense-making' when doing school word problems (leading to computationally based solutions to absurd problems such as in "There are 26 sheep and 10 goats on a ship. How old is the captain?" Answer: $26 - 10 = 16$) can be considered as evidence for the importance of the situatedness of mathematical cognition and learning (Verschaffel et al., 2000). From an educational perspective, the situated view particularly implies the importance of interaction and collaboration in mathematics learning as well as of the importance of a proper understanding of the role of tools in mathematical thinking and learning.

Teaching Mathematics

For a long time, mathematical learners worldwide received school-based instruction according to a 'mechanistic' or 'skills approach' – an instructional approach that is based on the view that mathematics learning is a highly individual activity consisting mainly of absorbing and memorizing a fixed body of fragmented and decontextualized knowledge and procedural skills directly transmitted by the teacher. Baroody (2003: p. 17) describes it as follows:

> The skills approach, with its focus on memorization of basic skills by rote (…), is based on the assumption that mathematical knowledge is simply a collection of socially useful information (facts, rules, formulas, and procedures). Except for the mathematically gifted, children are viewed as "empty vessels," largely helpless, and perhaps incapable of understanding many aspects of school mathematics. The aim of math instruction is to inform them about how to do mathematics. Proponents of the skills approach (e.g., the "back-to-basics" movement) believe that the most efficient way to transmit information is by means of direct instruction and practice – without taking the time to promote understanding about the whys of procedures. The teacher directs all aspects of the learning process to ensure efficient instruction (transmittal and mastery) of basic skills.

In the skills approach, a teacher who wants his or her pupils to master the algorithm for long division demonstrates the

subsequent steps of the algorithm on the blackboard several times, and then instructs the pupils to copy these steps on long lists of similar problems and provides corrective feedback until the pupils master this algorithmic procedure, without explaining where the algorithm comes from, why it works, and how to choose between this algorithm and other computational methods (such as mental arithmetic or estimation). Against the background of the above-mentioned view that mathematical proficiency comprises the integrated mastery of various kinds of competencies and that mathematics learning is an active, cumulative, and situated process of knowledge building and skill acquisition, many mathematics educators have criticized this traditional 'mechanistic' or 'skills approach' and proposed, implemented, and tested reform-based instructional approaches, which aim at the mastery of all aspects of mathematical proficiency and which are characterized by more conceptually-, inquiry- and/or problem-based forms of learning.

For example, Lampert (1990) has designed a learning environment that aims at promoting meaning construction and understanding of multiplication in fourth graders by connecting and integrating principled conceptual knowledge (e.g., the principles of additive and multiplicative composition, associativity, commutativity, and the distributive property of multiplication over addition) with their computational skills. She starts from familiar and realistic problems to allow children to use and explore their informal prior knowledge, and practices collaborative instruction whereby she engages in cooperative work and discussion with the whole class. Students are solicited to propose and invent alternative solutions to problems that are then discussed, including their explanation and justification. It is obvious that this learning environment also embodies a classroom climate and culture that differs fundamentally from what is typical of traditional mathematics lessons.

A second and more comprehensive example is Realistic Mathematics Education (RME) developed in the Netherlands. RME was the Dutch answer to the internationally felt need, in the late 1960s and early 1970s, to reform mathematics education. It was a reaction to both the then prevailing 'mechanistic' or 'skills approach' to mathematics education, and the structuralistic 'New Math' movement that was expected to dominate the (Western) math educational world in those days (De Corte and Verschaffel, 2006; Treffers, 1987). RME conceives mathematics learning essentially as doing mathematics starting from the study of phenomena in the real world as topics for mathematical modeling, and resulting in the reinvention of mathematical knowledge. Based on this fundamental conception of doing mathematics, the design of 'realistic' learning environments is guided by a set of five interrelated principles: (1) learning mathematics is a constructive activity, (2) progressing toward higher levels of abstraction, (3) encouraging students' free production and reflection, (4) learning through social interaction and cooperation, and (5) interconnecting knowledge components and skills (Treffers, 1987). Of course, these general instructional design principles of RME have to be refined and adapted to specific mathematical topics and educational contexts, before they become operational and can be put to an empirical test. Typical examples of such local RME theories have been developed for the teaching of arithmetic algorithms, fractions, and basic statistics, and have been implemented and tested in the context of 'design experiments' (Wittmann, 1995), which have reported results that are, in general, quite positive for the RME approach.

A third example is Schoenfeld's (1985) instructional approach for teaching problem solving to college students. Starting from the idea (developed on the basis of several detailed observational studies) that using heuristics in conjunction with metacognitive executive control skills and appropriate beliefs is an essential feature of expert problem solving, Schoenfeld developed a teaching approach that focuses on the heuristic, metacognitive, and affective aspects of mathematical problem solving. Besides extensive use of modeling by the teacher to demonstrate how an expert applies these various elements of mathematical expertise, and whole class discussions, ample use is made of small-group problem solving, whereby the teacher acts as a consultant, regularly asking questions such as: what are you doing, why are you doing this, and how will it help to find the final solution? The results of this instructional approach were very positive, in the sense that both the problem-solving performance and processes of students who had followed his course became more expert-like.

During the past decades, similar efforts to reform mathematics education, from elementary school to university, have been undertaken in many other countries, all of which embody to some degree the above-mentioned ideas about what mathematics essentially is and how it can be optimally learnt and taught, such as, the conception of mathematics as human activity, the constructivist view of learning, the crucial role of students' prior – informal as well as formal – knowledge, the orientation toward understanding and problem solving, the importance of social interaction and collaboration in doing and learning mathematics, the need to embed mathematics learning into realistic contexts, and to create a genuine mathematics classroom culture. Generally speaking, the researchers of these studies report promising results that demonstrate that these reform-based learning environments, if properly implemented, can lead to fundamental changes in the way children acquire mathematical knowledge, skills, and beliefs, and make them more autonomous and more motivated mathematical learners and problem solvers.

However, the evaluation of these reform-based frameworks, approaches, and materials is not univocally positive. Critics have argued that convincing empirical evidence in favor of this reform-based approach is lacking (because of methodological shortcomings in these design experiments), that there are indications that gains in certain domains and aspects of mathematics learning are paralleled with losses in other domains, and that the wider implementation of the envisioned reform-based ideas and materials and methods would require competencies from teachers – mathematical as well as didactical – that go far beyond what they currently possess (Baroody, 2003; KNAW, 2009).

During the past decade, these attacks against these reform-based views on and curricula and textbooks for mathematics education have been most obvious in the United States, under the (unfortunate) metaphor of Math Wars (Schoenfeld, 2004), also showing recent signs of export to other countries. Interestingly, the debate about the content and methods of mathematics education is accompanied by a deep disagreement

about how the merits of different approaches to mathematics education should be assessed. The National Mathematics Advisory Panel Report (United States Department of Education, 2008), for instance, almost completely eliminated mathematics education research from its consideration of 'what works' by adopting rigid methodological criteria that largely ruled out studies other than large-scale randomized controlled trials. In various sharp reactions the community of mathematics educators (e.g., Cobb and Jackson, 2008; Greer, 2012) objected to this attempt to conform mathematics educators to problematically narrow criteria for rigorous designs, reliable and valid assessment instruments, and significant results (Sriraman and English, 2010).

However, most mathematics educators by no means reject experimental and quantitatively oriented methodologies, as long as they are combined and balanced with other methods that do respect the complex and multi-dimensional nature of mathematical thinking and learning, and of the educational and broader cultural environments in which it occurs (Cobb and Jackson, 2008). Moreover, it would be naive to expect that empirical research alone – of whatever type it is – will yield a clear and conclusive answer as to what kind of instructional approach is most valuable for teaching mathematics, not only because of the complexity of the field or the diversity of its subdomains, but also because of the serious differences in beliefs about and valuations of what mathematics is after all and why it is important for learners and for people and society in general (Greer, 2012).

Matrifocality

Raymond T Smith, University of Chicago, Chicago, IL, USA

This article is reproduced from the previous edition, volume 14, pp. 9416–9418, © 2001, Elsevier Ltd.

Abstract

The term 'matrifocal family' was introduced in the 1950s to analyze the process through which Afro–Guyanese women, in their role as mothers, became the focus of affective ties while men were increasingly marginal to the complex of domestic relations, but not necessarily absent from them. Its use spread, first in the Caribbean and then globally, though it has too often been confused with female-headed households. Worldwide changes in the status of women, the nature of conjugal relations, patterns of child-rearing, and the configuration of household structures, suggest the continuing relevance of the term 'matrifocality' as an analytical concept taking note of the relation among class, status, gender, conjugal, and domestic relations. The term has achieved a much wider popular currency and is now used to refer to almost any situation in which women are prominent.

Introduction: Definition and Derivation of the Term

Although there is no generally agreed upon definition of matrifocality, and indeed the term has been applied so variously that its meaning is quite vague, for the purposes of this article it is defined as follows: 'matrifocality is a property of kinship systems where the complex of affective ties among mother and children assumes a structural prominence because of the diminution (but not disappearance) of male authority in domestic relations.'

The term 'matrifocal family' was introduced to solve a problem of empirical description as well as to suggest an alternative theoretical view of the domestic organization of rural African-Americans in the then British Guiana (Smith, 1956). After considering (and rejecting) such terms as 'matricentral' and 'matriarchal' to refer to the internal relations among members of households, many of which were female headed (but certainly not all), the term 'matrifocal' was used as follows:

> The household group tends to be matri-focal in the sense that a woman in the status of 'mother' is usually the *de facto* leader of the group, and conversely the husband-father, although *de jure* head of the household group (if present), is usually marginal to the complex of internal relationships of the group. By 'marginal' we mean that he associates relatively infrequently with the other members of the group, and is on the fringe of the effective ties which bind the group together. (Smith, 1956)

In the last sentence the words "effective ties" is an undetected printer's error; in the manuscript it reads "affective ties" which was, and is, the author's intention.

The term was quickly taken up and widely used in Caribbean studies though not consistently or without debate; it frequently was confused with 'female-headed.' Since the 1950s both the use and the meaning of matrifocality has been extended beyond the Caribbean as it tracked the worldwide revolution in gender relations, in marriage patterns, and in domestic relations. Its appeal as a less precise, but more evocative, expression has value in pointing to the changes in kinship practices and gender relations in the context of broader socioeconomic and political changes, but for the analysis of those changes something closer to its original meaning is necessary.

The Term 'Matrifocal' and the Context of Its Introduction

Beginning in the 1930s an upsurge of labor unrest and nationalism in the Caribbean colonies led to policies of 'development and welfare.' Family life became a central issue in those policies, on the assumption that anything differing from middle-class European family ideals was unsuited to the modern world. Sociology had developed quite complex theories purporting to show that the isolated nuclear family of man, wife, and children was not only the most highly evolved, but also the most adapted to modern industrial society with its complex division of labor and high degree of social mobility based on male occupations. These ideas converged with the assumption – the false assumption – that a stable nuclear family based upon legal marriage is natural, being found in all human societies (*see* Family: The Anthropology of the Concept and its History). Given these assumptions, households containing women with children by several fathers, unstable conjugal relations, conjugal partners living together without being legally married, were all considered to be deviant, abnormal, or pathological.

More technical anthropological analysis had shown that counting descent through females did not alter male dominance; however, matrilineal descent, that is, the inheritance or transmission of power and economic resources from a man to his sister's sons (rather than to his own sons), could lead to unstable marriage and complicated domestic organization when the contrary pulls of marriage and parenthood on the one hand, and loyalty to the lineage on the other, precipitated an array of varying domestic arrangements (see Fortes, 1949).

The analysis of matrilineal systems was important for countering the ethnocentric assumptions of nuclear family universality and paternal authority patterns; unfortunately, it had little influence on the emerging discussions of matrifocality. A widely cited publication was a paper entitled *A Survey of the Consanguine or Matrifocal Family* in which the author defined the matrifocal family as 'a co-residential kinship group which

includes no regularly present male in the role of husband-father' (Kunstadter, 1963). Given this definition, it is not surprising that the author classifies extreme matrilineal cases where women and children live with, and under the jurisdiction of, the woman's brother, as 'matrifocal,' but it also excludes cases where a husband father is actually present, and abandons the criterion specified by Smith (1956) who later stated that, the term 'matrifocal' – specifically intended to convey that it is women in their role as mothers who come to be the focus of relationships, rather than head of the household as such – the nuclear family is both ideally normal, and a real stage in the development of practically all domestic groups (Smith, 1973). Kunstadter also ignored the developmental cycle of domestic relations, pioneered by Fortes in his study of Ashanti. It was central to the original concept of matrifocality because it analyzed the changing focus of domestic authority and cohesion as children are born and mature. Kunstadter's paper, because of its place of publication, its title, its simplicity, and apparent authority, became the most widely cited source on matrifocality, drastically modifying its meaning by equating it with a static definition of female-headed households.

Family Policy and the Search for the Causes of Poverty

In European and North American societies it had long been assumed that poverty and disorganized families were at once the cause and the result of each other. These assumptions were given vigorous new life, and a decided racial slant, by the declaration in 1965 of a 'War on Poverty' in the US, when it became evident that the material well-being of the African-American population actually had deteriorated in spite of revolutionary civil rights legislation. A report by the United States Department of Labor (1965) purported to find the cause of continuing social deprivation in family structure, and more specifically in the 'matriarchal' pattern of Negro families in which the roles of husbands and wives are reversed. The term matrifocal had been introduced precisely to avoid this kind of false reading of the data, but both critics and defenders of this report managed to negate that original meaning, moving toward Kunstadter's view and equating it with matriarchal or female headed.

It is ironic that most of the suggested cures for poverty require a return to traditional gender roles (on the assumption that a stable nuclear family based upon marriage is both natural and necessary for the adequate socialization of children), while at the same time gender roles themselves were undergoing a radical transformation as women of all classes increasingly entered the labor force, bore children out of wedlock, and frequently raised them in households without a male head.

Matrifocality and Feminism

It was inevitable that the term would be taken up in the new wave of feminism that has done so much to transform societies in the latter quarter of the twentieth century. The idea of a stage of human evolution in which women were dominant is not new. The Swiss jurist Bachofen (1861) took Herodotus's descriptions of the matriarchal system of the Lycians as its point of departure, but contributed to nineteenth-century speculations about the development of patriarchy out of primitive promiscuity through a stage of matriarchy (*see* Kinship in Anthropology). The same kind of research into myth and religion has been employed by recent theorists of cognitive or symbolic archaeology, most notably Marija Gimbutas and her followers. Admirers and opponents alike of Gimbutas's theory of a woman-centered stage of European social development have made free use of matrifocality in their commentaries, referring to a matrifocal stage in the development of European civilization (Marler, 1997). This kind of generalized use has spread far outside anthropological circles, sometimes being used to refer to almost any female focussed activity, whether motherhood is involved or not. The term has also found its way into discussions of animal behavior.

The Analytic Dimension of Matrifocality

Matrifocality has been identified by anthropologists in societies too numerous to list here, and including such varied cases as Java, Portugal, Thailand, Italy, South Africa, and Brazil, as well as the *locus classicus* of the Caribbean and urban North America. Many have used the broader definition of female-headed or female-dominated households and pointed to the economic difficulties faced by husband-fathers as a presumed cause of matrifocality, thus, implicitly (if not explicitly) characterizing such families as abnormal forms of the nuclear family. However, all raise the theoretical issue of the relations among class, status, gender, and the family. Matrifocality is never an isolated condition or a simple cultural trait; it must always be considered in the context of the entire social system of which it is a part.

One of the first studies to address that issue was the study of marriage in the context of race and class in nineteenth century Cuba (Martinez-Alier, 1974). She showed the effect upon domestic organization of the marginalization of colored men and women in a society where racial purity and legal marriage defined social status and social honor. In later work Smith (1987) argued that the matrifocal family in the Anglophone Caribbean is an integral part of the complex status system that emerged out of the *slave* regime, where men of higher status were able to marry equals and enter nonlegal unions (coresidential or visiting) with women of lower status, thus institutionalizing a dual marriage system that operated at all levels of the social system. It is not poverty that produces matrifocal families but the combination of societal norms, status, and property considerations stressing nuclear families based on legal marriage, coexisting with nonlegal unions, illegitimacy, and matrifocal families at all levels of the hierarchy for those whose unions do not serve to conserve either status or significant property. Another example is O'Neill's demonstration that in rural Portugal, illegitimacy and matrifocal families are closely related to the status and land-owning structure of local communities (O'Neill, 1987).

Abstract

Marcel Mauss (1872–1950) was the most influential social scientist of the French School of Sociology headed by his uncle Emile Durkheim. Though an armchair scholar, having been teaching all his life at Parisian institutions of erudition (*Ecole Pratique des Hautes Etudes* – since 1901, *Collège de France* – after 1931), he is generally considered as the founding father of contemporary French social antropology. His work comprises epoch-making studies on comparative religion (Sacrifice, Magic, Eskimo rituals), social cohesion (especially the *Essay on Gift*, 1925), the arbitrary and multifunctional nature of cultural facts ('total social phenomena'), the prevalence of social determinism on individual behaviour and the social origin of mental categories (time, space, the self, etc.).

The father figure of contemporary social and cultural anthropology in France, Mauss was among the most influential social scientists of the early twentieth century. His scholarly activities and achievements were closely connected to the birth, organization, and coming to power in the French academe of the 'Sociological School' headed by Emile Durkheim and gathering among other luminaries Célestin Bouglé, Maurice Halbwachs, Robert Hertz, Henri Hubert, or Francois Simiand, the intellectual heritage of which is still being largely claimed, discussed, and studied worldwide (see *Durkheimian Studies*, Oxford) as one of the major foundation acts of modern social sciences proper.

Mauss was born on 10 May 1872 in Epinal (Vosges county) in a middle class Jewish family long established in Eastern France and having fully adopted the pattern of French Liberal patriotism. His personal career followed in many respects the rise of the first generation of famous French–Jewish intellectuals represented by Bergson, Durkheim, or Lucien Lévy–Bruhl. He shared with them their Republican commitment, notably as a young activist engaged in the battle in defense of Captain Dreyfus, as one of the earliest contributors (reporting on the cooperative movement) to the socialist journal *L'Humanité* founded by Jean Jaurès and, in the interwar years, as a dedicated expert of the (anti-Bolshevik) French socialist party (notably in matters financial and those related to the stock exchange). Mauss died on 10 February 1950 in Paris.

With formal university training in philosophy (a quasi must for would-be social scientists in his time), Mauss skipped the then almost inescapable stint of secondary school teaching, but also the stages of a normal academic career in the network ofthe Faculties of Letters. Several study trips and stays in Britain, Holland, and Germany enabled him to commit himself from the outstart to research and the training of scholars. He was first appointed as a lecturer on archaic religions (*The Religion of Peoples Without Civilization*) at the 5th Section (Sciences of Religion) of the *Ecole Pratique des Hautes Etudes* (1901), a unique agency housed in, but independent from, the Sorbonne and aiming at the instruction of specialists in various fields of erudition. He combined later (1926) these courses with seminars on 'descriptive ethnology' at the newly founded *Institut d'Ethnologie* under the aegis of the Sorbonne, only to occupy the chair of sociology at the *Collège de France* (1931), an even more prestigious institution of higher learning. While lecturing there he also shared in a Socratic manner with a number of (often mature) students the insights of a uniquely ingenious armchair anthropologist, until he was forced to early retirement under the German occupation in 1941. His positions in these both central, but academically marginal Parisian institutions helped him to achieve a rather atypical career of a scholar exclusively dedicated to research on exotic societies without visiting any of them and producing neither a thesis, nor even books proper, but, instead, a number of substantial studies which – though highly specialized by their thematic focus – refer equally to various tribal civilizations of Australia, Amerindia, Africa, and Oceania as well as to a vast variety of relevant 'social facts' of the Hindu, Hebrew, or Muslim world.

His education, intellectual development, and academic options were directed and supervised by Durkheim, his uncle and life long tutor. Their works – though intimately linked – appear to be considerably divergent. With the benefit of historical hindsight Mauss is credited nowadays as a less theory-bound, more inspiring and heuristically rewarding ancestor for contemporary successors of the 'French School of Sociology,' his personal impact extending upon many significant anthropologists, sociologists, folklorists, political scientists, social psychologists, or even human geographers or social historians starting a career in France after the First World War, especially after 1945. His association with Durkheim took a decisive form by his participation in the empirical elaboration of databanks for Durkheim's *Suicide* (1897) and continued, more importantly, with the editorial work of the *Année sociologique* (12 volumes between 1898 and 1913), the central scholarly organ of the 'Sociological School.' This quasi yearly survey of relevant publications embodied the first major attempt since August Comte (see *Comte, Auguste (1798–1857)*) to organize empirically the burgeoning social sciences into an inter-related system of disciplines. In charge of a large sector of the *Année* covering 'religious sociology,' Mauss became the author of one-quarter, approximately, of the 10 000 odd pages of review articles published in the *Année* under Durkheim, and took over the direction of the *Année* – transformed in the interwar years into the irregularly published *Annales sociologiques* – following the uncle's untimely death in 1917.

In the division of labor of what became the 'French School of Sociology' Mauss was, from the outset, dealt out the sector or

archaic civilizations, especially that of 'primitive religion,' strategic field for the experimentation of Durkheim's basic methodological precepts. In this view indeed the main 'social functions' appear to be apprehensible in a straightforward form in archaic societies, so much so that they may inform the interpretation of more complex societal realities as well. Thus, tribal societies – not without ambiguity – can be equated to the simplest, the most essential, and the historically earliest patterns of social organization. To boot, following the 'religious turn' occurring around 1896 in Durkheim's scholarly evolution, religion was considered as central among 'social representations' or objectivations of 'collective consciousness,' instrumental in the integration of archaic and, by implication, of all social formations. Hence the epistemological priority granted to the study of 'elementary religion' and the allocation of such pursuits to sociology proper as a master discipline, whatever the degree of development, power, extension, or complexity of societies concerned could be. Thus most of Mauss' work centered on comparative problems related to belief systems, rituals, and mental habits, and other collective practices serving as a foundation for 'social cohesion' in extra-European and pre-industrial civilizations, could qualify for being sociological, without much reference to anthropology, ethnology, ethnography, or folklore; such terms being practically absent from the topical listing of 'branches of social sciences' in the *Année*.

Mauss' major early studies are the outcome of his brotherly collaboration with Henri Hubert, the ancient historian and archeologist of the 'Sociological School.' They deal with the social functions of '*Sacrifice*' (1899) (biblographic details of Mauss' studies are listed by years of publication at the end of the third voume of his *Oeuvres* (pp. 642–94) and propose 'A general theory of magic' (1904), to which Mauss added a number of personal essays, especially those concerning 'The sources of magic power in Australian societies' (1904) and the first part of his unpublished (and unpresented!) doctoral dissertation on 'Prayer' (1909). Some of these essays will be published in their common book *(Mélanges d'histoire des religions*, 1909), where the authors offer in their introduction the outline of a sociological theory of religion. Denominational systems of faith are social facts and should hence be put on the agenda of sociology. They divide the life world of societies into a sacred and a secular (profane) sphere. The former is invested with essential collective values, so much so that most if not all moral customs, legal, educational, artistic, technical, and scientific practices display religious foundations. Mauss' first ever review article discussed already a book on 'Religion and the origin of penal law' (1896). In the light of his and his companions' comparative studies concerning 'religious representations' (including totemism, 'positive and negative rites' and their mythical rationalizations, the Melanesian notion of *mana* as the paradigm of socio-religious force, the religious origins of values – like that of money, etc.), religion emerges as a fundamental 'social function,' even if secularized modern societies tend to replace it by functional equivalents (like patriotic rituals) to bring about a desired degree of integration.

Mauss will be less systematic (some would say, less dogmatic) than his uncle in the generalization and theoretical exploitation of observations gained from the study of archaic religions. But he shares with Durkheim the conviction that the social prevails over the individual among norms commanding human behavior and, more specifically, that sociohistorical models are the sources of mental categories epitomized in the 'reason' or 'logos' of Western philosophy, permitting the intelligence of time, space, causality, genres, force, etc., though this approach was often condemned as 'sociocentrism' or 'sociological imperialism' by contemporary critics. In concrete terms Mauss' main interest lay, on the one hand, in the exploration of interconnections between collective practices and ideas, in the manner how mental elaborations respond to the organizational patterns of societies contributing thus to their cohesion and, on the other hand, in the exemplification of the arbitrary nature of cultural facts which become meaningful in particular social configurations only. The first focus would lead to decisive methodological insights for the sociology (or the social history) of knowledge. The latter would inspire developments in structuralist social anthropology.

Major statements about the covariation and the fundamental integrity of various fields of collective conduct are made in the essay of comparative anthropology published together with Durkheim on *Primitive social classifications* (1903) and in a *Study of social morphology*, produced with the collaboration of Mauss' disciple Henri Beuchat on *Seasonal Changes of Eskimo Societies* (1906).

In the much cited (and not less criticized) first study a vast array of evidence, drawn from a number of extremely different Australian and American societies, is presented and analyzed in order to illustrate the functional unity of societies (as totalities) in which mental habits, religious ideas, and even basic categories guiding the perception of environment and other – residential, economic, technical – practices are demonstrably interconnected. Thus, 'the classification of things reproduces that of people,' as exemplified in many tribal civilizations where membership in phratries, matrimonial classes, clans, gender, or age groups serves as a principle for the organization of religious and other social activities as well as for the interpretation of reality in 'logical classes.' The spatial situation of the tribe is a basic model for categories of orientation, like cardinal points. Hence the intimation, that categories of reasoning, instead of following universal patterns, are sociohistorical products and even modern science owes some of its principles to primitive categorizations. Such results will later encourage Mauss to affirm the pretensions of 'social anthropology to be once in the position of substituting itself to philosophy by drafting the history of the human mind.'

The study of Eskimo life offers a more empirical evidence for a case of covariation in time of the material substratum – morphology – of societies ('the mass, density, shape, and composition of human groups') and the moral, religious, and legal aspects of collective existence. The approach is, exceptionally, not comparative – though references are made to other exotic and even European societies too – only to be more closely focused on a privileged example where even the pattern of settlement of families concerned (gathering in winter, dispersion in summer) differs with the seasons, together with the intensity of social interactions, religious activities, and kinship relations. Winter represents the high point of social togetherness accompanied by festivities, the unity of residence of partner families, and various forms of economic, sexual, and

emotional exchange among their members, generating in them a strong sense of political and moral integrity.

In the second part of his career after World War I Mauss' work appears to be thematically more diversified without losing its initial foci centered upon the ways and means by which society determines individual behavior and the conditions of collective 'solidarity' or 'cohesion,' the latter – while realized thanks to contingent or 'arbitrary' assets – forming an operational whole called 'culture' or 'civilization.' This helps to restate the historical and ethnographically localized nature of mental categories. These problems and ideas inform some major studies published by Mauss in his elderly years like 'Relations between psychology and sociology' (1924), 'The physical impact of the idea of death suggested by society' (1926), 'The problem of civilisations' (1929), 'Bodily techniques' (1935), 'A category of the mind, the concept of person, that of the self' (1938). But the masterpiece emerging from that period remains the famous comparative essay *On Gift, Form and Reason of Exchange in Archaic Societies* (1925).

'The gift' is a vast, though fragmentary accomplishment of a program to study primitive economic systems where much of the exchange of goods is carried out by apparent donations accompanied by other – mostly symbolic or ritual – services, which make it a 'total social phenomenon.' The main focus of the study is what some North American Indians name *potlatch*, a system of 'total exchange' of 'agonistic' nature, whereby rivalry between groups, relationships of prestige and force, forms of social inequality and alliance are expressed, confirmed and enforced. The exchange in question may equally imply the circulation of goods, honors, courtesy, rituals, women, etc., and its essential principle is the obligation to offer and accept as well as return gifts, even if the things given hold purely symbolic value only, since many acts of donation consist of the ritualized destruction of a maximum of goods – which is the very meaning of the *potlatch*. Destruction of valuables is in such systems an essential source of power and prestige by the demonstration of one's possessions and the capacity to dispense with them on an apparently voluntary, but in fact strictly compulsory basis. Survivals of such arrangements, proper to several archaic societies, can be traced in the code of behavior of industrial societies as well. Modern contractual trading relations are still often completed or accompanied by moral customs of inescapable reciprocities grounded in gifts, sacrifice, symbolic grants, acts of generosity, the generalization and institutionalization of which (possibly in the regime of social welfare) appears in Mauss' view as a desirable development. He will extend the scope of the study of 'total social facts' in several essays, especially in one on 'Joking relationships' (1926), socially organized delivery of jokes and insults among kins, destined to strengthen the cohesion of the clan by the enforcement of verbal reciprocities.

Mauss' scholarly achievement has left a considerable mark on the social sciences in France and elsewhere. In contemporary French sociological tradition he is considered – alongside may be with Maurice Halbwachs – as the most 'legitimate' ancestor from the 'Sociological School.' The historic importance of his work has been selectively and critically received but warmly appraised by men like Pierre Bourdieu (who is holding a chair of sociology illustrated by Mauss at the *Collège de France*), Roger Caillois, Georges Dumézil, Louis Dumont, Georges Gurvitch, Michel Leiris, Claude Lévi-Strauss (who succeeded Mauss at the *Collège de France*).

McDonaldization

George Ritzer and Chih-Chin Chen, University of Maryland, College Park, MD, USA

Abstract

McDonaldization is Ritzer's theoretical adaptation of Max Weber's theory of rationalization. While Weber uses the bureaucracy as the model for the process of rationalization, Ritzer uses the fast-food restaurant, especially McDonald's, as the contemporary paradigm of the process. He defines McDonaldization as "the process by which the principles of the fast-food restaurant are coming to dominate more and more sectors of American society as well as of the rest of the world."

The McDonaldization of Society

The process of McDonaldization as well as the following principles that lie at its base have, in various ways and forms, found their way into most organizations and institutions in American society and as well as into many other parts of the world (Ritzer, 2010):

Efficiency: is defined as the optimum method of getting from one point to another. Emblematic of efficiency is McDonald's drive-through that reduces to the minimum the necessary time spent on ordering food and getting the needed service. Efficiency is accomplished through a series of modifications in the system designed to accomplish a wide range of ends. The efficiency of the McDonaldized system has its roots in Weber's bureaucracy, Ford's assembly line, and Taylor's scientific management. This culminated in a highly efficient method of accomplishing virtually any task. An example outside the fast-food industry is the McDonaldized educational system, which seeks to produce test results in the most efficient manner possible through the use of multiple choice exams and scantron grading system.

Calculability: involves an emphasis on the quantitative aspects of products and services such as size, price, and speed. McDonald's does not tout its products because of their exquisite quality or distinctive nature, but emphasizes their size. The best example is the 'Big Mac.' Like McDonald's, other highly McDonaldized companies such as IKEA and Walmart compete on the basis of low price, rather than on the high quality of goods and services provided.

Predictability: is the assurance that products, services, and settings will be very similar, if not entirely identical, over time and in all locales. There are no surprises or shocks in these settings and in the products offered. Instead, there is the safety and comfort of experiencing the same processes and products over and over.

Control: is the power exerted over both customers and employees of McDonaldized settings. Such control is accomplished by, for example, a material structure (e.g., the drive-through) that restricts actions available to consumers, scripted behavior on the part of employees, and a strict control on work processes. Interaction between consumers and employees is highly restricted and controlled. The possibility of any unwanted human elements occurring is thereby reduced.

These principles make McDonaldization a major aspect of, and force in, the process of globalization. McDonaldization is a key example of what Ritzer (2003, 2007) calls "the globalization of nothing." In this context, nothing is any social form that is centrally conceived, centrally controlled, and lacking in distinctive content. McDonald's is an example of 'nothing' since its 35 000 restaurants around the world are conceived and controlled by headquarters in Illinois and every McDonald's follows the same basic model.

The Irrationality of Rationality

Ritzer's critique of McDonaldization is not to be found in the four principles per se, but rather mainly in the idea of *the irrationality of rationality*. McDonaldization has provided many benefits for management, but many disadvantages for the consumers. The efficiency for restaurants often results in inefficiency for customers. McDonald's customers must often wait in line or stuck in traffic jams in the drive-through lane. Walmart and Costco customers must often buy things in bulk and some of it often proves unnecessary and inefficient to transport and store. Automated phone services often keep callers waiting and transferred from one extension to another, when callers could have received much more efficient service from a trained customer service representative. Seemingly, efficient methods and processes often prove inefficient for customers, and sometimes even for organizations and their employees.

McDonaldization does not necessarily produce the cheapest products and services for customers. It greatly reduces the manufacturing, distribution, and the processing cost for McDonaldized organizations, but this reduction is not fully reflected in the sale prices. A meal for four in a fast-food restaurant is priced much higher than its cost of production, to say nothing of what its nutritional value would suggest. The same amount of money spent on ingredients for home cooking would produce a much more wholesome meal. Disney World, a highly McDonaldized entertainment setting, is becoming more and more expensive, while the actual satisfaction seems to diminish. Some years ago, a journalist calculated that due to, among other things, long drives and waits in the park, his 5-day trip to Disney World resulted in a grand total of 6 h and 47 min of actual fun at the cost of $261 per hour (it would be much more expensive today) (Garfield, 1991).

In a McDonaldized society, more and more work is being performed by the consumers. For example, they take on the work of bank tellers when using ATMs, the work of waiters and buspersons when ordering, eating, and cleaning up in the fast-food restaurants, and the work of customer service representatives when working their way through the automated phone directories. Customers are forced to perform more and more

work, but they are not paid for their labor. Ritzer and Jurgenson (2010; Ritzer et al., 2012) have urged a theoretical shift in scholars' mind-set from a focus on either producer or consumer to one that focuses on consumers who work (as well as producers who consume). In other words, the focus should be on 'prosumers.' In order to understand the true nature and the social logic hidden in the structure of economic activities, we have to look at economic activity in its totality that involves an intertwined and codependent fusion of production and consumption.

Following another aspect of Weber's work, McDonaldized settings can also be seen as disenchanted (Ritzer, 2010). That is they have lost, if they ever had, their magic. Every process, object, and interaction is spelled out, structured, and routinized to the minutest detail and followed closely by both employees and customers. The excitement of the unknown, the mystery of the unpredictable, and people's idiosyncratic interactions are controlled or eliminated by McDonaldized systems. Those who manage McDonaldized settings care less about how good and enjoyable their services and goods are, but focus more on such things as the number of customers served and of the products sold. McDonaldization's pursuit of quantity has reduced or eliminated its ability to create magical experiences through, for example, the pursuit of authenticity and quality.

McDonaldization tends to dehumanize those involved in the process. It tends to turn employees into nonthinking robots who mindlessly follow scripts and customers into little more than livestock fed on a food conveyor belt. Both are transformed into cogs and wheels of the machine, which is a McDonaldized system. Neither is allowed much ability to think and act independently or to deviate much from the scripts. The fantasy (or nightmare) McDonaldization constructs for its customers is one of mechanical dystopia in which everything and everyone is routinized, standardized, and preprogrammed. In McDonaldized systems, one can choose to be livestock or robot, but never the human of free will and agency.

McDonaldization has produced "Islands of the living dead" (Ritzer, 2003), as opposed to Weber's 'iron cage.' McDonaldization has transformed each setting into an individual island of McDonaldized processes and rules, but there is no overarching bureaucratized society with an iron cage that structures all settings to operate in the same way. The efficiency produced in one setting may not provide the same level of efficiency in a different setting. Thus, people move from island to island (e.g., fast-food restaurant to Walmart) and are led to act like the 'living dead' in each setting. Governed by the principles of McDonaldization, each island deadens people by restricting their freedom to think and act independently. The only true freedom available to people is in the non- or less-McDonaldized spaces between islands of the living dead.

The Advantages of McDonaldization

In spite of its numerous problems, McDonaldization has its advantages. It has helped to produce a monumental abundance for society. A wide variety of goods and services have become accessible to portions of society that found it difficult or impossible to obtain them in the past, at least at affordable prices. For example, the supply of medicine and other essentials for survival are now provided to more people than ever, and this is made possible by McDonaldizing the processes and organizations involved in the production of pharmaceuticals. The speed by which goods and services are delivered has increased significantly (e.g., FedEx). The convenience of efficiency also appeals to people who are working longer and have less time to spare. McDonaldized settings' uniform treatment of employees and customers also decreases discrimination based on race, sex, and class.

Theorizing and Studying McDonaldization

A number of other theories relate to the theory of McDonaldization. Some are similar, some are antithetical, and some extend the ideas into fields unrelated to consumption. Benjamin Barber's (1992, 2010) "Jihad vs McWorld" applied the idea of McWorld to the field of political science. He explores the struggle between McDonaldized process and entities, 'McWorld,' and indigenous and local entities, 'Jihad.' While Jihads in various places attempt to retain their local distinctiveness and authenticity, McWorld eliminates differences, leaving the same predictable product and ideologies everywhere. Barber attributes the forces behind McWorld and its global expansion to neoliberal economic forces and active corporate control. Barber believes that McWorld will eventually win out over Jihad and homogenize the entire planet due to its financial and political advantages. Ritzer (2003, 2007) proposed a similar duality "something vs nothing" to explain the tension in the globalization process. While something involves forms locally conceived and controlled with distinctive content, nothing, as pointed out above, encompasses forms that are centrally conceived and controlled, and that lack distinctive content. Ritzer argues that something is rapidly losing ground in the face of the spread of nothing in a process he calls "grobalization of nothing," but he also leaves the room for a dialectical relationship with the "glocalization of something." This offers some hope in an otherwise gloomy view of a world increasingly dominated by the nothingness associated, especially, with McDonaldized System.

Some approaches such as "Starbuckization," "IKEAization," and "eBayization" offer alternative explanations and paradigms to deal with the changing landscape of society. Starbuckization offers a softened image of McDonaldization with theatrical performances making the customers feel welcome to stay, rather than being harried and rushed in McDonald's. IKEAization emphasizes the transfer of work from employees to customers, like McDonaldization's "putting customers to work." eBayization offers an alternative picture of market-directed activity (rather than McDonaldization's centrally controlled system), a variety of products (as opposed to McDonald's limited and predetermined menu), and unpredictable offerings (in contrast to McDonald's predictable products). Even though all of these processes offer interesting and useful perspectives, their structure and leading principles continue to rely heavily on the principles of McDonaldization. Starbucks' success is built on the premise of selling coffee in a McDonaldized grab-n-go fashion; it would never be able to sustain itself on the revenue from the relatively few sit-in customers. IKEA's products are highly McDonaldized and can even be thought of

as pushing the control over customers beyond the confines of its geospatial settings, as customers are likely to assemble furniture at home in accord with instruction provided by IKEA. eBay's variety and unpredictability are made possible by utilizing a highly McDonaldized infrastructure and interface for all listings and sales.

Many scholars have studied McDonaldization empirically. Drane (2002, 2012) examined the ways in which the church adopts the principles of McDonaldization. Hayes (2006) studied higher education and its degree of McDonaldization in, for example, the increase in the student–faculty ratio and the pumping out of more and more graduates. Timimi's (2010) work on children's mental health describes the McDonaldized process we have developed to deal with children's aberrant behavior. The expansionistic and increasingly universal nature of McDonaldization has led to many cross-cultural studies (Ram, 2004; Caldwell, 2004; Iqbal, 2011; Heslop, 2011; Peak, 2012).

Critiquing and Resisting McDonaldization

There are a number of criticisms of McDonaldization and critiques of how well the theory depicts and explains social reality. Many of the authors in Smart (1999) have critiqued the theory on empirical grounds. For example, McDonaldization does not mesh well with the current academic discourse on the postmodern society's transition to a post-Fordist mode of production. McDonaldization produces identical objects with a Fordist mode of production, and thus is not in accord with the differentiation and distinction postmodern consumers seek in today's commodities and services. Second, the highly predictable and secure 'comfort' McDonaldization is supposed to provide runs counter to the increasing risk and unpredictability of contemporary risk society (Beck, 1992/2006). McDonaldization is also heavily criticized for being a school of elitist thought in accord with Horkheimer and Adorno's (1969) critique of popular culture. Other authors in the Smart volume criticize Ritzer for oversimplification and neglecting the nuanced operation and management maneuvering of local units on the ground, as well as the advantages of the corporate system that enables the smooth operation of massive entities like McDonald's or Walmart.

There are many examples of resistance to the expansion of both McDonald's restaurants and McDonaldization. Some (such as McLibel) directly target McDonald's by pointing out its environmental, cultural, and health threats to society. Others choose to tackle the process itself and the ideology behind it. The Slow Food movement is the most famous organization seeking to protect and promote traditional ways of food production, preparation, and dining from the threat of McDonaldized food items and restaurants. Less noticeable struggles in local communities are reported by the media from time to time.

McDonaldization and the Internet

The promise of large-scale de-McDonaldization can be glimpsed in the realm of the Internet. The advent of Web 2.0 shifts much content production from a centralized source to the users. Wikipedia, Facebook, Craiglist, Twitter, etc., are all examples of de-McDonaldization. Much of their content runs counter to the four principles of McDonaldization (Jurgenson, 2010). They are often inefficient (requiring large investments of time and resources), unquantifiable, unpredictable, and less controlled. However, we should not overlook the fact that they are made possible by highly efficient, calculable, predictable, and highly controlled programming language and digital infrastructure. This points us to a very different picture in which both McDonaldization and de-McDonaldization exist simultaneously, as de-McDonaldized content accumulates on an increasingly McDonaldized platforms.

Mead, George Herbert (1863–1931)

Daniel R Huebner, The University of North Carolina at Greensboro, Greensboro, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

American pragmatist philosopher George Herbert Mead (1863–1931) has had a major influence in the social sciences through his examinations of the processes of symbolic communication and the genesis of the social self. He developed his philosophy in dialogue with unique influences from empirical science, critical philosophy, and the progressive social reforms in which he was heavily involved during his eventful career. Although his ideas were known to colleagues and students at the University of Chicago in the early twentieth century, his subsequent influence has largely been through volumes compiled from disparate sources and published after his death.

George Herbert Mead (1863–1931) was an American philosopher, considered to be one of the classical representatives of pragmatism, along with Charles S. Peirce, William James, and John Dewey. For Mead, Dewey was a particularly important interlocutor and colleague. Mead's ideas have had a major influence in the behavioral and social sciences, especially in sociology and social psychology, where he is best known for his theory of the development and process of human symbolic communication and for his account of the social nature and genesis of the 'self.' These notions have been central to the formation of the 'symbolic interactionism' perspective in sociology and have led Mead to be considered a foundational theorist in that discipline. The following sections examine Mead's philosophy in the context of his education, teaching, and social reform efforts and discuss the dominant interpretations made of his work.

Life and Context

Early Life and Education

George Herbert Mead was born to Rev. Hiram Mead and Elizabeth Storrs (*née* Billings) Mead in the village of South Hadley, Massachusetts on 27 February 1863. Hiram Mead came from a large, educated New England family, and several of his siblings also pursued Protestant religious callings. Hiram was the pastor of the First Congregationalist Church of South Hadley when George was born, and he remained in that position until appointed to the chair of Sacred Rhetoric and Pastoral Theology at Oberlin Theological Seminary in 1869, at which time the family moved to Ohio. Elizabeth Mead also came from a large, educated New England family, which including Elizabeth's twin sister Harriet. She was educated at Ipswich Female Seminary and taught in secondary schools prior to her marriage. After Hiram's death in 1881, Elizabeth began teaching English composition at Oberlin College and, later, Abbot Academy, before becoming president of Mount Holyoke College in 1890. Documentation on George Mead's early life is somewhat sparse, but it is clear that he and his older sister Alice were raised in an environment that highly valued broad education with emphasis on religion and service. The biographical information in this article draws primarily upon work by Joas (1985), Cook (1993), and Huebner (2014).

After attending the 'preparatory' department connected with Oberlin College, George Mead attended Oberlin from 1879 to 1883, graduating with a bachelor's degree in 'Philosophy and the Arts.' He became close friends with classmate Henry Northrup Castle in the last 2 years of college, bonding over mutual interests in philosophy and literature. As in many private American colleges of the nineteenth century, Oberlin's humanities faculty taught an 'Intuitionist' philosophy that emphasized the freedom of the will and the intuitive perception and experience of the world. As Mead and Castle were exposed to the critical, materialist doctrines of modern scientific researchers from their science classes, however, they became increasingly skeptical about this philosophy. They also coedited and contributed to the student news and literary paper, the *Oberlin Review*, during their final year of college, 1882–83. When Henry's older sister, Helen Kingsbury Castle, came to Oberlin to attend school that year, Mead met his future wife for the first time, although they would not marry for almost another decade. Helen and Henry were the youngest children of one of the most prominent American settler families in the (then independent) Kingdom of Hawaii. Their parents had arrived in the islands with early American missionaries, but quickly took up business for themselves in sugar production, shipping, and general merchandise. As a result, Helen and Henry were heirs to the massive company Castle & Cooke, a fact that would play a major role in Mead's life.

After college, Mead took a series of jobs to help support himself and his mother while he struggled to find a meaningful direction for his adult life. From 1883 to 1887, he taught at an elementary school, worked on railroad surveying crews, and tutored young men preparing for college. During this period, he wrestled with an increasing agnosticism, resulting at least in part from his independent study of critical philosophy and modern physical and evolutionary science. He considered possible careers, including starting a preparatory school or a literary magazine or pursuing some ameliorative work in the Christian ministry. However, Mead was too conflicted to pursue a religious calling and he did not have the resources for the others. Meanwhile Henry Castle, who had worked for a period in his brother's law office in Honolulu and had

attended courses in Germany, decided to attend graduate school at Harvard in 1886. Henry's letters to Mead, and his trip to visit Henry that year, seem to have helped Mead to decide on pursuit of graduate education in philosophy.

Mead attended Harvard beginning in the fall of 1887 as an advanced undergraduate (Harvard did not accept his degree from Oberlin). He roomed with Henry and took courses with Josiah Royce, George Herbert Palmer, and others. Although documentation is sparse, Mead's views on the self, symbolic communication, the history of science, and social progress seem to evince influences from Royce's idealist philosophy. At the end of the first year, Mead took the oral examination for an honors degree, and his performance impressed foundational psychologist and pragmatist philosopher William James. Although Mead did not take courses with James, he was invited to tutor James' son at their country house in the summer of 1888, and he received encouragement from James to apply for fellowships to pursue further graduate study in Germany.

As a result, Mead began coursework at the University of Leipzig in the winter 1888–89 semester, where he studied with Wilhelm Wundt, among others, and again roomed with Henry Castle. Although Wundt was perhaps the leading psychologist in Germany and directed what is often considered the first psychological laboratory, Mead took only his philosophy course on 'metaphysics.' After that semester, Mead transferred to the University of Berlin (Friedrich-Wilhelms-Universität). The circumstances of Mead's move are not entirely clear, but recent work has shown that William James recommended Mead to Hermann Ebbinghaus, Berlin's premier experimental psychologist. By this time, Mead had decided to focus his study on 'physiological psychology' because, according to Castle, this was a topic upon which he could pursue critical inquiry without fear of 'anathema and excommunication' from the 'all-potent Evangelicalism' of American Protestantism.

At Berlin, Mead became a laboratory assistant in Ebbinghaus's laboratory, working on psychophysical experiments. He took advanced courses in anatomy and physiology with Wilhelm Waldeyer and Hermann Munk that focused on recent discoveries about the central nervous system. From Wilhelm Dilthey, he took courses in ethics and the history of philosophy and planned to write a dissertation on the construction of the human conception of space through the cooperation of the hand and eye. Dilthey was a leading epistemologist of the human sciences, arguing that descriptive and interpretative methods were more adequate to the study of the meaningful structure of human experience than were natural scientific experiments and explanations. This period appears to have had a major impact on Mead's subsequent work, introducing him to the philosophical questions entailed in scientific discovery and raising questions about the nature of human experience and consciousness. He also became interested in the social democratic labor movement, the developmental psychology of children, and the psychological treatment of ethics during his time in Germany.

Professional Career and Social Activism

Prior to completing his degree at Berlin, Mead was offered a position as instructor in philosophy at the University of Michigan beginning in fall 1891 by the department's chair, John Dewey. Although he maintained hopes of completing his Berlin degree *in absentia*, Mead never obtained a graduate diploma. During his last year in Germany, Mead had become engaged to Helen Castle. They married in Berlin on 1 October 1891, just before traveling to Ann Arbor, Michigan for George's first semester there. Mead's position required him to teach courses in physiological psychology and the history of philosophy, including recent scientific developments such as evolutionary theory. Mead also took charge of the new psychological laboratory, where he prepared specimens of neurological tissue, performed psychological experiments, observed behaviors of microscopic and complex animals, and considered evidence from pathological psychology. On 30 November 1892, Helen Mead gave birth to their only child, Henry Castle Albert Mead, named for his uncles Henry Castle and Rev. Albert Swing (the husband of George's sister, Alice).

Mead stayed at the University of Michigan for 3 years, the last as assistant professor. During that time, Dewey and Mead, along with instructor Alfred H. Lloyd, formulated a unique 'functional psychology' perspective that brought the new findings in biology and psychology to bear on the problems of idealist philosophy. They were critical of theories of a mental 'substance' or definite mental structures, and instead proposed to examine fundamental philosophical and psychological phenomena such as consciousness and emotion in terms of the normal, physiological, and social processes of action in which they were implicated.

In 1894, Dewey was offered the chair in philosophy at the newly formed University of Chicago, and as part of his acceptance he negotiated an offer for Mead. Chicago was one of the new comprehensive research universities that developed in the United States in the late nineteenth century, largely following the German university model. At Chicago, they became part of a close-knit cohort of innovative faculty, and they formed early ties with the social and biological sciences. Until Dewey left in 1904–05 for Columbia University, the philosophy department also contained the faculties of psychology and education, and it administered the psychology laboratory and experimental pedagogical schools.

Throughout his 36 years at the University of Chicago, Mead offered a wide variety of courses. He taught a large number on the history of philosophy and the history of science, including all periods but especially ancient Greek thought and all fields and major authors of modern philosophy. His classes on the epistemology and methodology of the physical, psychological, and social sciences also evince his interest in the philosophical problems of science. When he moved to Chicago he ceased offering courses in physiological psychology and gave up directorship of a psychological laboratory, but in exchange he began offering what may be the earliest courses on 'comparative psychology' in any American college, from 1894 through 1911. In these courses, he examined the development of intelligence by tracing the increasingly complex forms of control of environments by biological organisms. During that period, Mead also actively observed and offered suggestions on the studies of animal behavior conducted by students in the psychology laboratory.

Beginning in 1900, he taught 'social psychology,' first intermittently, and then regularly after 1908. From 1918 on, this course was reformulated as 'Advanced Social Psychology' to reflect the growing literature in the field and the newly instated introductory social psychology courses in Chicago's

psychology and sociology departments. This was the course that became famous after his death through the book *Mind, Self, and Society* (Mead, 2015[1934]). After 1913, he taught periodic seminars on 'social consciousness' and other related social psychological questions, and from 1905 to 1910 he taught courses on the philosophy of education and the teaching of science. In the last decade of his career, he became increasingly interested in the controversies arising from relativity theory and contemporary physics, and he taught several advanced courses on these issues. In addition to his courses at the University of Chicago and other lectures at local professional schools of social workers, Mead gave over 200 public speeches. Indeed, he was undoubtedly known more widely during his lifetime for his public reform efforts than for his contributions to professional philosophy or social thought.

During the late nineteenth and early twentieth centuries, Chicago was rapidly expanding and industrializing, and it was the scene of major contentions over labor rights, immigration, race relations, public education, and political corruption. The city was a center of the American Progressive Movement, and George and Helen Mead were heavily involved in these social reform efforts. The Meads fostered a relationship with Jane Addams and the 'Hull House' social settlement in their first months in Chicago. They advocated publicly on behalf of women's suffrage, the rights of immigrants and minorities, birth control education, compensation for prison labor, development of juvenile justice institutions, and increased opportunities for education and employment of women. In 1910–11, when the garment workers of Chicago went on strike over working conditions, Helen met with the striking women and donated to their support while George worked as part of the semiofficial 'Citizen's Committee' to develop recommendations for arbitration.

The Meads were involved in many efforts to democratize education in Chicago and elsewhere. In addition, George Mead helped found the 'Chicago Physiological School,' an early experimental school dedicated to the study of children with disabilities; the 'Juvenile Psychopathic Institute' (later the 'Institute for Juvenile Research') dedicated to the study of juvenile delinquency; and the University of Chicago 'Laboratory School,' an experimental school dedicated to participatory pedagogical methods that make use of the spontaneous interests and activities of students. In these and other endeavors, Mead was an advocate of coordinating systematic data regarding education and social conditions. He helped develop plans for a municipal 'bureau of social research' that would coordinate the data collected from various public and private agencies concerning the citizens of Chicago, an effort that ultimately resulted in creation of the city's Public Welfare Bureau.

The Meads also promoted many of these same efforts in Hawaii, where Helen's family members were prominent officials and philanthropists, and where the Meads made 13 extended stays together from 1897 to 1924. The Castles were strong supporters of the revolution against the hereditary monarch in 1893 that established the short-lived 'Republic of Hawaii' and the subsequent US Territory of Hawaii. On several occasions, Mead accompanied the Territorial Governor and other officials on hiking tours of the islands, examining the conditions of native and immigrant life, agriculture, and geology, and he participated in public discussions on US annexation, public education, and municipal governance. He even officially represented the Territory as their delegate to the 'National Farm Land Congress' in 1909. The Mead's also helped arrange extended stays in Hawaii for Jane Addams, John and Alice Dewey, and progressive activist Harriet Park Thomas (first wife of sociologist W.I. Thomas), among others.

George Mead's influence in social reform was probably at its peak during the 1910s, when he was the president of the City Club of Chicago and held official positions in the University of Chicago Settlement League, the Immigrants' Protective League, and the Vocational Supervision League. During this period, he helped prepare reports on Chicago's public school system, vocational education efforts, public library, and the living and working conditions for people living in its 'packinghouse' district. Although the Meads were early supporters of the 'Woman's Peace Party' that argued against the United States entering World War I, by late 1917 George Mead began to advocate intervention in order to combat perceived imperialism and promote democratic institutions. In this turn, he was like many American intellectuals, including President Woodrow Wilson. During this period, Mead's published work sought to define the acceptable grounds for pacifism and conscientious objection to war, the social psychological origins of hostility, the possibilities for peaceful expansion of social consciousness, and the uses of nationalism for the promotion of infrastructure-building and reform.

The Meads' son Henry became a foreign correspondent for the Chicago Daily News stationed in Berlin during the early months of World War I. After a period back in the United States, Henry volunteered for the military and was sent as an officer to France. In August 1918, he was seriously wounded by shrapnel in battle and spent several weeks in a military hospital while his family tensely awaited word. Henry's wife, Irene Tufts Mead (daughter of George's colleague James H. Tufts), volunteered to aid wounded women and children in France during the war as well. During the same time, Mead was in charge of supervising the curriculum for several midwestern states of a newly founded civics education program called the 'War Issues Course' instituted in Student Army Training Corps throughout the country.

After the war, the Meads were members of the League to Enforce Peace and prominent advocates for adoption of the Covenant of the League of Nations. This advocacy brought controversy, as George Mead was accused by US Senator Medill McCormick of improperly using his position at the City Club to promote a partisan, personal belief. Accounts of Mead's intellectual biography have often pointed to the trauma of World War I as a major turning point in Mead's public persona (Cook, 1993; Deegan, 2008; Joas, 1985). Although he quit some of his more prominent posts in the aftermath, Mead remained active in the Vocational Supervision League and the Chicago Council on Foreign Relations until near the end of his life. This career-spanning dedication to social reform work clearly influenced his understanding of democratic governance, the nature of scientific inquiry, and social consciousness.

Late in his career, Mead began to receive professional recognition. In 1929, he taught courses at the University of

California, Berkeley as the honorary visiting Mills Professor of Philosophy, and in 1930, he gave the Carus Lectures, considered one of the highest honors awarded by the American Philosophical Association. The honor had been bestowed only twice before, to John Dewey and A.O. Lovejoy, and included publication of the lectures as a book by Open Court Publishing as part of the award.

At the same time, however, his late life was witness to illness and frustration. Helen Mead died on Christmas day 1929 following a period of declining health. The following year, Mead reluctantly accepted the interim chairmanship of the Chicago philosophy department when his longtime colleague, James H. Tufts, retired earlier than expected. He was faced with addressing the demands of the new university president, Robert M. Hutchins, who mishandled appointments by questioning the acumen of current philosophy faculty and attempting to appoint his acquaintances rather than the faculty's own recommended candidates at salaries higher than the sitting philosophy faculty (Cook, 1993). Mead quit his position in protest along with several junior faculty members in late 1930, and his action caused considerable controversy when it became public in February 1931. He planned to accept John Dewey's invitation to teach at Columbia University the following fall. However, he fell seriously ill and was forced to give up teaching the remainder of his courses at Chicago at the end of February 1931. He died on 26 April 1931 at the age of 68, in the Chicago home of his son and daughter-in-law.

The Work

The center of Mead's philosophy is typically considered his social psychology, which begins not with individual organisms but with an ongoing 'social process' consisting of humans cooperating in the accomplishment of a 'social act.' Drawing from Charles Darwin's analysis of the 'expression of emotions' in animals and Wilhelm Wundt's notion of 'gesture,' Mead proposed that organisms learn to respond to the movements of one another in ways that anticipate the further courses of action. When an organism responds to the early phases of another's action as if it indicated the complete act, that movement becomes a gesture or 'truncated act' that may serve as a 'sign' for the act as a whole. When organisms adjust back and forth to one another's gestures in guiding the course of action, there is a 'conversation of gestures.' In developing this theory, Mead sought not to presuppose an innate self-indicative faculty in the mind and instead to show that if humans appear to have this self-reflective or symbol-using capacity, then it must result from the interaction of fundamental organic features of the human species and the features of social action.

Gestures can come to have the same 'meaning' for all of the participants in an act when the participants learn to respond to their own gestures in the same way as those of others. This happens primarily through the 'vocal gesture,' because individuals can hear and respond to their own vocalizations in much the same way that they hear and respond to one another. As a result, what had been merely gestural signs become 'significant symbols' to the extent their utterance indicates the same set of actions for all those involved.

For Mead, the development of this symbolic capacity has enormous consequences. It allows humans to internalize and anticipate not only the action of others, but also their own action. Humans can respond virtually (that is, within the nervous system of the individual, rather than through external response) to gestures and can check or inhibit responses by the influence of other gestures. Indeed, Mead thought that this 'internalized conversation of gestures' constituted the fundamental process of rational thought. Because an individual's partners in social action have this same anthropological capacity, they can develop binding, reciprocal expectations regarding one another's behavior, and all those who share common meanings for some set of gestures constitute a 'universe of discourse.' The development of this symbolic communication fundamentally transforms the possibilities of social organization, by allowing for rational anticipation and planning, complex functional interdependence of social groups, and the possibility of progressive social change.

Mead proposed that humans 'take the role of the other' when they anticipate another's behavior. This concept is often misunderstood to mean that humans imaginatively project themselves into one another's places, but Mead explicitly sought to avoid a theory that relied on such mental projection or empathy. Additionally, individuals progressively develop the capacity to take the role of others toward their own actions, and thus they develop a consciousness of 'self' by treating their own action as a social object. In conduct, the self has two phases: the 'I' and the 'me.' The 'I' is the impulsive aspect of the self, which acts spontaneously in response to present situations. The 'me' is the internalization of the expectations of others through the course of experience, and serves to evaluate and structure the spontaneous responses of the 'I.' Each unique person or group that serves as a significant 'other' for the individual contributes to the internalization of a different 'me.' The integration of a unitary self requires the synthesis of these various responses in previous situations to numerous others into a coherent center of action and evaluation, and hence it is both a practical and moral problem for the individual.

Developmentally, the formation of the self happens through a series of stages. The earliest stage discussed by Mead is 'play,' in which a child acts out a course of conduct in a series of roles. The child takes on a new role when he or she responds to his or her own action in previous roles. This play is how the child practices and learns the situational expectations of various roles. In the 'game' stage, the child begins to anticipate and guide his or her conduct not by taking on various roles, but by the organization of one's responses to the expectations of several others into one coherent role. This organization is guided by the functions that the various others adopt within a group activity, such as the 'positions' in a baseball game, and learning to play the game means being able to anticipate the actions of the other players in relation to one's own position and respond appropriately.

The furthest stage in the formation of the self is the development of the 'generalized other' that occurs as the individual is able to orient his or her action toward the goals or values of the group action in which they are involved and to respond to those goals or values as a coherent 'other.' In this way, individuals develop the ability to evaluate and react to the group as a whole. Individual responsibility for one's actions and for the

direction of social action comes as the individual is able to identify that action with the self, and in that sense to be 'self-reflective.' Individuals can develop ever broader 'generalized others' to the extent that they orient their conduct toward more encompassing social action processes beyond the immediate groups and situations of which they are a part. This theory was key to Mead's advocacy of inclusive democratic participation, the development of international cooperation, and pragmatic ethics more generally.

The principles of Mead's social psychology are also central to the other aspects of his philosophy. For example, the capacity to manipulate the surrounding environment (especially by use of hands) combined with symbolic and gestural communication allows humans to create and reconstruct a common physical environment of objects and to represent different perspectives on that environment. These capacities are key to the philosophy of nature and to the formation of scientific knowledge. The experiences of individual scientists are essential to the progress of modern science: each scientist begins with some socially shared conception of the nature of the objects under study, but when his or her experience testing the objects is inconsistent with that conception the investigator must reconstruct the object in a way that is consistent with all new and old observations. In this sense, they act as fully developed selves responding to and enlarging a community. In Mead's last few years, he worked to apply these notions to metaphysical or 'cosmological' questions of relativity, emphasizing the objective location of different 'perspectives' in nature and their fundamental 'sociality,' as well as the novel or creative emergence of both past and future from the present.

Influence of Mead's Thought

During Mead's life he was known widely for his reform work, and his philosophical work received significant attention almost exclusively from his closest colleagues and students at the University of Chicago in philosophy, psychology, and the social sciences. He was an important part of the so-called Chicago School of American pragmatist philosophy associated with John Dewey that was closely tied with the development of functionalist psychology, institutionalist economics, behavioral political science, empirical sociology, and progressive pedagogy. From 1920 to 1931, his 'Advanced Social Psychology' courses received additional attention from University of Chicago sociology students, because his former student Ellsworth Faris began teaching an 'introductory' social psychology course that instructed sociologists in Mead's ideas and served as an informal prerequisite for Mead's advanced course. Faris also wrote a large number of articles and reviews in sociology publications, which argued that Mead's philosophy offered fundamental insights for sociology.

These efforts notably influenced students of the so-called Chicago School of sociology to learn aspects of Mead's social psychology. Herbert Blumer, who was a student at the University of Chicago from 1923 to 1928, has no doubt had the largest influence on the subsequent interpretations of Mead in sociology. He was also the person who took over teaching Mead's 'Advanced Social Psychology' course when Mead died. Blumer (1969) drew heavily from Mead in developing 'Symbolic Interactionismor,' and as a result Mead came to be taught and understood as the quintessential progenitor of this perspective. As Symbolic Interactionism and related phenomenological perspectives have been incorporated into mainstream sociology, Mead has become recognized as a classical sociological theorist.

Also important to the development of Mead's reputation has been the reception of his work in post–World War II social theory, especially in the work of German authors Arnold Gehlen, Hans Joas, Jürgen Habermas, and Axel Honneth. Joas (1985), in particular, considers Mead a central figure linking American pragmatism to continental philosophy and offering novel solutions to the problems of critical philosophy. Habermas' influential *Theory of Communicative Action* and other writings treat Mead's philosophy as a crucial resource in the formulation of his 'communicative action' framework and 'discourse ethics.'

The predominant source material for most commentaries on Mead's ideas has been a series of books published after Mead's death, and especially *Mind, Self, and Society: From the Standpoint of a Social Behaviorist* (Mead, 2015[1934]), which alone accounts for the vast majority of citations to Mead since the mid-twentieth century. Within days of Mead's death, members of his family began consulting with his colleagues and former students on the possibility of publishing a memorial or legacy for him. Although Mead had written several major journal articles and a large number of book reviews, paper abstracts, newspaper articles, editorial notes, committee reports, encyclopedia entries, and conference proceedings, he had never written a book-length work. From 1932 to 1938, four major works resulted from these efforts and were published under Mead's name: *The Philosophy of the Present* (Mead, 1932) based on the transcript of Mead's well-received 'Carus Lectures'; *Mind, Self, and Society* based on edited transcripts and student notes from Mead's social psychology courses; *Movements of Thought in the Nineteenth Century* (Mead, 1936) based on sets of notes from a course of the same name; and *The Philosophy of the Act* (Mead, 1938) compiled from manuscript fragments written by Mead in the last decade of his life and fragments from various student notes and papers. Since the 1960s, several other publications attributed to Mead have appeared, including manuscript papers and speeches that Mead gave and students' notes from several more of his courses in social psychology, philosophy of education, and history of philosophy. And beginning with the *Selected Writings* (Mead, 1964), there have been several attempts to publish in an accessible format his most important published articles and papers.

The volumes of posthumously published materials have been a frequent source of controversy, because of the lack of transparency in how they were constructed and because of the seemingly idiosyncratic representation they give of Mead's philosophy. For example, the term 'social behaviorist,' used to characterize Mead's work, appears only in *Mind, Self, and Society* and was added to the text by the volume's editor, Charles Morris (later known for his work in 'semiotics'). More generally, the order and internal structure of the volumes do not directly reflect the logical structure or development of Mead's philosophy. Instead, they are heavily influenced by the editorial processes through which the volumes were composed. In this light, some criticisms of Mead, such as

those that point out his supposed lack of focus on emotions or on social structure, result at least in part from the popularity of these posthumously constructed volumes rather than Mead's own body of published works, public speeches, and classroom teachings.

As interest in classical American pragmatism revived in the late twentieth century, Mead began to receive renewed critical attention from philosophers, historians, and others. With this increased attention to Mead from several fields and the criticisms of dominant interpretations of Mead has also come a growing critical literature on Mead's intellectual biography, the historical context of his ideas, and the formation of his intellectual legacy, including a four-volume collection of 'critical assessments' (Hamilton, 1992). Most recently, Mead's work has found new audiences in some branches of science studies, cognitive science, and ecology. However, Mead's ideas have continued to have their largest and most consistent influence on the discipline of sociology.

Abstract

This article gives details on the life and professional career of American cultural anthropologist Margaret Mead, at the time of her death in 1978 the most famous anthropologist in the United States. It also outlines and follows what is known of the Mead–Freeman controversy, New Zealand anthropologist Derek Freeman's severe critiquing of her Samoan fieldwork and of *Coming of Age in Samoa* after her death. The controversy lasted an intense 18 years until Freeman's own death in 2001. That year was also the centennial of Margaret Mead's birth, and seems to have marked a turn away from the controversy and more interest in pursuing other lines of Margaret Mead scholarship.

Margaret Mead, noted twentieth-century American cultural anthropologist, was born on 16 December 1901, in Philadelphia, Pennsylvania, to Emily Fogg Mead, sociologist and social activist, and Edward Sherwood Mead, economist and professor at the Wharton School of Finance and Commerce at the University of Pennsylvania. The oldest child, she later had a brother and three sisters. She grew up in a household that had its share of troubles – a younger sister died at 18 months, her father and mother once came close to divorce. But it was also a household open to new ideas and social change. Her mother was an ardent advocate for the vote for women; her paternal grandmother, Martha Ramsay Mead, who lived with them, was, along with her mother, interested in experimenting with the latest ideas in education. Her father, a more conservative progressive, also acted as devil's advocate in lively debates over issues at mealtimes.

Her education was a combination of home schooling and local schools. She attended Buckingham Friends School and graduated from Doylestown High School, both in Bucks County, outside of Philadelphia. She spent her first year of college at DePauw University in Indiana, but found herself an outsider there. She transferred to Barnard, a highly regarded women's college in New York City, where she made lifelong friends and from which she graduated in the spring of 1923.

In the fall after graduation she married Luther Cressman, a young man she had met in Bucks County and been engaged to since leaving for DePauw. He was a college graduate and a graduate of General Theological Seminary in New York, which he attended while she was at Barnard. For both, the ideal marriage was an equal partnership.

They attended graduate school at Columbia University in New York City together, he in sociology, she receiving her master's degree in psychology, then her PhD in anthropology. At Columbia she was a student of Franz Boas, the preeminent anthropologist in the United States, and part of a distinguished anthropological community that included Melville Herskovits, Ruth Bunzel, Esther Goldfrank, and Ruth Benedict, who began as a mentor, and through the graduate school years became a colleague, close friend, and lover. A bisexual, throughout her life Mead developed relationships with both men and women. During this time she also met anthropologists from outside New York, of whom Edward Sapir was the most important. They had a brief relationship that ended while she was in Samoa.

She defended her dissertation, a piece of library research titled, *An Inquiry into the Question of Cultural Stability in Polynesia*, in the spring of 1925 (published in 1928). After accepting a position as an assistant curator at the American Museum of Natural History in New York upon her return, that fall she set off for her first field trip to American Samoa in the Pacific. She was gone altogether 9 months, while Luther studied in Europe. The result of that field trip was her book, *Coming of Age in Samoa* (1928), which showed Americans there could be a different system of morality in which premarital sex was accepted, and adolescence itself was not necessarily a time of 'storm and stress.' This book became a best-seller and began the process, which, by the time of her death, made her the best-known anthropologist in the United States. With this book she began a pattern she continued on later field trips, of writing a popular book for the general public, and also a scholarly monograph. In this case the monograph was *Social Organization of Manu'a* (1930). Both anthropologist Robert Redfield and Ralph Linton gave it favorable reviews. Redfield wrote, "The documentation that was lacking in *Coming of Age in Samoa* is given in this book. It is a monograph of exceptional merit" (Redfield, 1931).

On the trip home, she met New Zealander Reo Fortune, on his way to Britain to study psychology. They fell in love and over the course of 2 years of internal struggle she and Luther decided to divorce. In 1928, she married Reo, who had changed his field of study to anthropology and had already taken his first field trip to the Dobu people in the Pacific. They immediately embarked on their first field trip together, to the Manus people of the Admiralty Islands in the Pacific. This resulted in her book, *Growing Up in New Guinea* (1930), a study of the socialization and education of Manus children. The monograph paired with this popular book was *Kinship in the Admiralty Islands* (1934).

She took two other field trips with Fortune. The first, a summer trip to the American West, resulted in her book *The Changing Culture of an Indian Tribe* (1932), which studied assimilation among the Omaha Indians. The second, a return to the Pacific, this time the mainland of New Guinea, resulted in *Sex and Temperament* (1935), a comparative study of three New Guinea peoples, the Arapesh, Mundugumor, and Tchambuli, which gave evidence for the first time of the constructed nature of gender systems. Prior to this, gender had been viewed as biologically innate. The monograph that

accompanied this popular book ultimately became the five-volume series called *The Mountain Arapesh* (1938–49). During this field trip, problems in their marriage came to a head, resulting in Mead and Fortune's divorce on their return from the field. In 1936, Mead married British anthropologist Gregory Bateson, whom she had met and fallen in love with in New Guinea, and they set out for their first field trip together to Bali in the Pacific, which resulted in their coauthored book, *Balinese Character: A Photographic Analysis* (1942). After this field trip, their daughter and her only child, Mary Catherine Bateson, was born in 1939.

During World War II, Mead served as Executive Secretary of the National Research Council's Committee on Food Habits, which did serious research on nutrition planning and cultural food problems, such as how to help people used to rice use white flour. She wrote a pioneering popular book, *And Keep Your Powder Dry* (1942), the first by an anthropologist to attempt to use anthropological insights and models to deal with a nonindigenous culture, that of the United States as a whole.

After the war ended, she became involved with Ruth Benedict in a project studying nonindigenous cultures around the world titled Research in Contemporary Cultures, popularly known as National Culture studies. When Benedict died in 1948, Mead took over as director of the project and brought it to a conclusion in 1952. Sometime in the late 1940s, after Benedict's death, Mead also began a long-term relationship with anthropologist Rhoda Metraux, which lasted until the end of her life. In 1949, using information from the eight cultures she had done fieldwork in, she wrote *Male and Female: A Study of the Sexes in a Changing World*. In 1950, she and Gregory Bateson divorced, the war having drawn them apart.

In the 1950s, Mead decided to revisit the Manus in the Pacific, to see what a difference 25 years had made for them. The result was *New Lives for Old: Cultural Transformation – Manus, 1928–53* (1956). This began a pattern of revisiting old fieldwork sites that continued almost until her death that resulted in several other shorter publications.

Mead wrote many other books and articles after World War II. Increasingly she emphasized working with colleagues outside anthropology for interdisciplinary insights, such as psychoanalyst Martha Wolfenstein, with whom she edited *Childhood in Contemporary Cultures* (1955) and with photographer Ken Heyman in *Family* (1965), or those within anthropology willing to do interdisciplinary work, such as Ray Birdwhistell who studied kinesics, or body language as it was popularly known. She examined topics such as how communication processes affect cultural change. She studied ekistics, the science of human settlements.

In 1961, she agreed to write columns for *Redbook Magazine*, a popular woman's magazine in the United States. These began to appear in 1962. This, coupled with her many appearances on television talk shows and radio, along with her lectures around the United States and throughout the world, made her a celebrity. She retired as a full curator at the American Museum of Natural History in 1969.

In 1970, she published *Culture and Commitment: A Study of the Generation Gap*, one of her most successful popular books after World War II, and in 1971 published a conversation between herself and African-American author James Baldwin, titled *A Rap on Race*. Her autobiography, *Blackberry Winter*, appeared in 1972. Still the most popular anthropologist in America, she developed pancreatic cancer and died in New York City, on 15 November 1978, at the age of 76.

Mead was most noted in the profession of anthropology as a founder and leader of the American 'Culture and Personality' school of anthropology, which, in the 1930s and 1940s, tried to meld interdisciplinary, particularly psychological, ideas and methodologies with those of anthropology. Mead pioneered the use of psychological testing among indigenous populations, worked with psychologists and psychoanalysts to develop or test theories, and fostered a wide variety of interdisciplinary connections throughout her life. After World War II, she also became known as an advocate of anthropological studies of nonindigenous peoples. She was recognized for her pioneering use of audio–visual techniques in the field, and for her continuing efforts to develop field training and new techniques for use in the field.

During her lifetime, Mead played a leadership role in anthropology and science. She was elected to membership in the National Academy of Sciences in 1975, and that same year became president of the American Association for the Advancement of Science. She had been a founder and president of the Society for Applied Anthropology (1940), and president of the World Federation of Mental Health (1956–57), and the American Anthropological Association (1960). She received over 40 awards during her lifetime, including the Viking Medal in general anthropology and, after her death, the Presidential Medal of Freedom.

In American culture and to the world at large, at the time of her death Mead was a celebrity, called in a *New York Times* editorial, 'the grandmother of the world.' She was listened to as an expert on child-rearing, the family, education, ecology, community building, and women's issues. She coined the phrase 'postmenopausal zest,' for the renewal and refocusing of women's energies after menopause. She was not afraid to be controversial, advocating trial marriage, the decriminalization of marijuana, and women's rights in the 1960s and 1970s.

But she had her critics, both during her lifetime and after. In her long career, Mead was criticized as well as lauded by other anthropologists for her popularizing efforts and for her interdisciplinary initiatives. Feminist Betty Friedan, in her 1963 book, *The Feminine Mystique*, accused Mead of falling into biological determinism in her book, *Male and Female*, and retarding the cause of women's rights through the 1950s. By the 1970s, educated New Guineans were beginning to look at her fieldwork critically as a product of colonial thinking. This was part of a general movement among former colonial peoples concerning anthropologists who had done fieldwork in their countries. By the 1990s, Mead's work, along with all the classic ethnographies, was being seriously critiqued by both indigenous scholars and Western scholars – in her case, in New Guinea she was criticized for a pro-Western stance in a time of colonialism and imperialism (Foerstel and Gilliam, 1992). Questions of implicit racism in her work were raised as well (Newman, 1999, 2004).

But the quality of her anthropological fieldwork was not seriously questioned until 5 years after her death. Then began what is now called the Mead–Freeman controversy, one of the longest standing intellectual controversies within academia, lasting 18 intense years until Freeman's death in 2001. There seems to be no one willing to keep his side going, and histories

of the controversy are now beginning to appear (Shankman, 2009). In his (1983) book, *Margaret Mead and Samoa: The Making and Unmaking of an Anthropological Myth*, Freeman attacked Mead's fieldwork in *Coming of Age in Samoa*, accusing her of total misunderstanding of Samoan culture and of describing Samoan culture and customs inaccurately. He depicted her as a young, naive girl deceived by Samoans who lied to her, or made up stories. He suggested that, as a young woman eager to succeed in the eyes of her mentor, Franz Boas, she skewed her work to prove his theories. While some took his side (e.g., Appell, 1984), Freeman's accusations stunned American anthropologists, many of whom critiqued Freeman and defended Mead. For example, American anthropologist Lowell Holmes, who had restudied Ta'u, a village where Mead had worked in American Samoa, while he had his own critiques of her work, saw her study overall as generally sound for its time and place (Holmes, 1983, 1987). Several researchers saw Samoan culture as containing elements of both Freeman's and Mead's studies (e.g., Shore, 1983; Scheper-Hughes, 1984; Feinberg, 1988). Others felt that both had overgeneralized (e.g., Côté, 1994; Orans, 1996). Many noted the differences between Western Samoa, where Freeman had done his fieldwork in the 1940s and 1960s, and American Samoa, where Mead did hers in the 1920s, and the role of the ethnographers' gender, age, and personality (e.g., Ember, 1985; Holmes, 1987; Côté, 1994). Several also noted Freeman's selective quoting and quoting out of context from other anthropologists, other writers on Samoa, and from Mead's work, which misrepresented these people's positions (e.g., Weiner, 1983; Holmes, 1987; Leacock, 1988, 1992; Shankman, 1996, 2009).

The argument continued for so long, partly because Freeman's accusations tapped into deeper questions anthropologists were especially wrestling with by the late 1980s and 1990s, and writing about Mead's or Freeman's work was a way to focus on them. One of these issues was a reevaluation of the roles of biology and culture within anthropology and social science. Freeman was seen as championing biological determinism and attacking Boas and Mead as cultural determinists (McDowell, 1991: C21; Levy, 1983; Strathern, 1983; Leacock, 1992). Another was the question whether anthropology was indeed a science or belonged instead in the humanities. Freeman's definitions of science and objectivity as he questioned Mead's work, in turn were questioned, and gave others an opportunity to reflect on the nature of science, and of objectivity, and on the nature of truth (e.g., Ember, 1985; Patience and Smith, 1986). Mead and Freeman also became part of a debate on ethnographic authority, and the nature of anthropology. The usefulness of ethnographies came under fire by the mid-1980s, as they were seen as artificial constructs, someone's idea of a different people, not necessarily the truth about a people (Clifford and Marcus, 1986). By the mid-1980s, other anthropologists had done fieldwork in Samoa: Lowell Holmes, James Côté, Martin Orans, and Paul Shankman. They criticized Mead, and found her work dated, but not, as Freeman did, totally wrong. Freeman had no room for a relative view of fieldwork. He believed there could only be one truth, not many, and his was the correct vision.

Thus the controversy also continued partly because Freeman worked to keep it alive. From 1983 through the next 18 years until his death in 2001, Freeman wrote at least 20 replies to his critics in academic and other journals, promoted a movie that espoused his views, *Margaret Mead and Samoa* (1988) and in 1996 promoted a play about himself by Australian playwright David Williamson, titled *Heretic*. Then in 1999 his second book on Mead came out, *The Fateful Hoaxing of Margaret Mead* (1999), in which his major argument was that Mead got her material on sexuality from two young girls who lied to her. They may have lied, or shaded the truth to Freeman, but it does not matter because other evidence in Mead's papers at the Library of Congress shows that she got her information from a variety of sources, not just the two girls highlighted in Freeman's book. At least one letter to Boas at the time shows that she knew of the potential of people lying to her.

Because she was such a celebrity in American society by the time of her death, the American mass media picked up the controversy quickly and spread it widely around the country. The first story actually came out in the *New York Times* 2 months before the book was published. Responses to Freeman's accusations lagged far behind the message that he had proved her wrong. The critique of Freeman's accusations largely took place in academic publications not read by the public (Shankman, 2009). Today, after almost 30 years, most anthropologists see her work as professional, if limited by time and place, but much of the general public ascribes to Freeman's view that he proved her wrong.

The year that Freeman died, 2001, was also the centennial of Margaret Mead's birth. Events were planned and carried out from the Library of Congress to California. This allowed the continuation of a reevaluation of Mead both personally and professionally in the following years, and the scholarship has generally ceased to focus on the Mead–Freeman controversy. The relationship between Ruth Benedict and Mead, privately and as colleagues learning from each other, became a subject of serious investigation (Lapsley, 1999; Banner, 2003). A collection of articles concerning Mead and Benedict focusing on 'feminism, race, and imperial visions' came out a year later (Banner and Janiewski, 2004). A volume of Mead's selected letters revealed hidden aspects of Mead's life and the people important to her (Caffrey and Francis, 2006). Another book examined Mead's celebrity and the images throughout her life which helped her maintain it; her role as an American Icon and as a 'representative figure,' meaning more to people in American culture than the sum of her own achievements during her lifetime (Lutkehaus, 2008). Another direction that the scholarship has taken so far is to review Mead's anthropological works from the 1920s to 1930s for what they tell readers about American culture rather than the culture of a non-American people (Molloy, 2008).

Mead left a legacy that includes the ideas of the relativity of adolescence and sexual mores that differ from culture to culture; the relative shape of the family, ranging from the nuclear, to widely extended by blood and adoption; the idea of the cultural construction of gender, of masculinity and femininity, as categories of human identity; and the connection between child-rearing practices and the shape of a culture.

Meaning and Rule Following

Abstract

According to a venerable tradition in philosophy and linguistics, expressions have meaning through being subject to conventions or rules. This claim has become a central topic of contemporary philosophy of language and mind in the wake of Wittgenstein and Kripke, largely because the normativity of meaning is regarded as a serious challenge to naturalism. One reaction to this challenge is to deny that the normativity of meaning is genuine. While there are 'semantic principles' specifying conditions for the correct application of expressions, these are either not genuinely normative or they are not in fact constitutive of meaning. But this dilemma can be defused if one distinguishes different dimensions of semantic normativity and pays attention to different types of mistakes that can afflict linguistic behavior. In particular, one needs to keep apart norms of truth and norms of meaning, regulative, and constitutive rules, and to appreciate the normative dimensions of the notion of correctness. The final section discusses the role of communally *shared* rules or conventions for language, in particular the age-old problem of circularity: how could such conventions be essential to language, given that the latter appears prerequisite for establishing and communicating conventions in the first place.

The idea that language is a *rule-guided activity* is as old as the study of language. It must not be confused with two other views about language involving normativity. We should distinguish:

supremacism: specific natural languages are superior to others, as in the idea that some languages are 'logical,' complex, or advanced, whereas others are 'primitive,' or in myths about a primordial or 'divine' language.

prescriptivism: one variety of a particular natural language (standard or written language) is inherently superior to all others and ought to be adopted by the whole community.

normativism: any form of language, including slang, dialects or even idiolects, is guided by rules, and it is the task of linguistics to identify the rules actually in force in a linguistic community.

Supremacism has been discredited by comparative linguistics (Sapir, 1921), and prescriptivism has few contemporary adherents (e.g., Dummett, 1993). By contrast, normativism continues to dominate among philosophers and linguists. The topic is not just pivotal to an adequate understanding of language; it epitomizes two fundamental controversies in contemporary thought.

The first is the conflict between *naturalists* and *normativists*. Naturalists believe that there is no genuine knowledge outside natural science (epistemological naturalism), and that the spatiotemporal phenomena studied by natural science exhaust what there is (ontological naturalism). Normativists have objected that logic, knowledge, and language depend on norms that cannot be captured by the factual descriptions and causal explanations of natural science.

The second is the conflict between *individualism* and *communitarianism*. According to individualists, the fundamental linguistic phenomenon is the idiolect, the language of an individual. According to communitarians, the fundamental phenomenon is that of a public language guided by shared conventions. Communitarians treat a language as a social practice or institution, which is more than the sum of individual speakers or idiolects. Both debates have profound repercussions for the behavioral and social sciences. Natural languages are the most striking and fundamental characteristics of human as opposed to animal communities. Whether they have an irreducible normative dimension is central to the question of what distinguishes us from animals. Furthermore, individualism is hospitable to the idea of an extremely fragmented society. We not only hold diverse beliefs and values, we need not even share a common language. Communitarians, by contrast, insist that we must share at least a linguistic medium in which to express conflicting viewpoints. And because they treat language as an intersubjective practice, they acknowledge and deplore phenomena such as 'language death' (Evans, 2010).

It is customary to distinguish different types of linguistic rules, following the orthodox division of semiotics: *syntactic* rules concern the combinatorial possibilities of linguistic expressions, in particular word arrangement within sentences; *semantic* or *lexical* rules determine the meaning or sense of words and sentences; *pragmatic* rules concern the use of words in communication, e.g., the speech-acts we perform by uttering sentences. This article focuses on semantic normativity.

Historical Background

Ever since Aristotle, there has been a broad consensus that words mean what they do as a result of human convention (*nomos*) rather than nature (*physis*). This consensus is epitomized by Peirce's distinction between three different types of signs – indices based on causal relations, icons based on similarity, and symbols based on conventions – and by Grice's (1989) dichotomy of natural and nonnatural meaning, as in 'these clouds mean rain' versus '*sesquipedalius* means "1 and ½ feet" in Latin.' The normative aspects of nonnatural meaning came to the fore through the later Wittgenstein. Wittgenstein attacked referentialist accounts. The meaning of an expression is not an object it stands for, but 'its use in the language' (1953: Section 43).

At the same time, Wittgenstein (like Chomsky afterwards) criticized behavioristic and causal theories of meaning (Ogden and Richards, 1923). These theories also explain the meaning of an expression by reference to its use. But the operative conception of use is purely causal. The meaning of a word is equated with the conditions, which *cause* a speaker to utter it and/or the *effects* that such utterances have on hearers.

Wittgenstein's alternative is a normative conception of use. The meaning of an utterance depends not on how it is actually understood, but on how *it is to be understood* within a linguistic community. What is semantically relevant about the use of an expression is neither the causes nor the effects of its utterance, nor the intentions with which speakers utter it, but its *correct* use. The linguistic meaning of expressions depends on general *rules*. These rules provide standards for the correct use of expressions, and thereby determine what it makes sense to say with the help of these expressions.

Kripke (1982; anticipated by Fogelin, 1976) portrays Wittgenstein as constructing a 'skeptical paradox' that questions the possibility of distinguishing between following and violating a rule, and thereby casts doubt on the very phenomenon of meaning. Furthermore, Kripke adopts a *communitarian* reading according to which Wittgenstein regarded rule following and language as inherently social. Kripke's tentative interpretation provoked hostile reactions from scholars (Baker and Hacker, 1984b; cp Kusch, 2006). The skeptical interpretation of Wittgenstein is wrong and the communitarin interpretation contentious at best (Glock, 1996). Nevertheless, there has been an extensive debate about 'Kripkenstein' on rule following, which is now conducted largely in blissful disregard for Wittgenstein's own writings (Miller and Wright, 2002). As regards the *normativity of meaning*, moreover, Kripke propounded ideas with Wittgensteinian roots and great substantive import.

The Kripkensteinian Paradox

According to Kripke's paradox, there is no set of facts that determines what rule R a speaker S is following in using an expression *e* and hence what S means by e. For all facts about the use of *e* by S up to a time t_1 are compatible not just with R but also with R′. I have been using '+' in the customary fashion, judging, for example, that $7+5=12$, $19+24=43$, etc. Accordingly, I appear to follow the rules of addition, and to mean the *plus* function by '+.' Inevitably, however, there are infinitely many sums that I have never performed. Suppose that I have never performed an operation '$x+y$' with x or y greater than 56 and am asked to calculate '$68+57$.' Everything about my use of '+' up to now is compatible with the possibility that I have been using '+' to mean the *quus* function, which is defined as follows:

- x quus $y = x+y$ for $x, y < 57$,
- x quus $y = 5$, in all other cases.

It is tempting to think that I meant plus in virtue of interpreting '$68+57$' as an instruction of the following kind: count out a set of 68 items; count out a set of 57 items; combine the two sets; count out the result. But what makes it the case that by 'counting,' I meant counting rather than quounting, an operation, which coincides with counting for numbers smaller than 57, yet yields 5 for all higher numbers? We have merely replaced a problem concerning a rule involving '+' by one concerning a rule involving 'count.' By pain of regress, rule following cannot be explained through invoking rules on how to apply rules.

The paradox questions neither the arithmetic truth that $68+57=125$ nor the reliability of my memory. At issue is not whether I can *know* that I meant plus by '+'; it is rather what facts, if any, *constitute* my following one rule rather than another and hence my meaning plus rather than quus. The threat is one of semantic *nihilism* rather than skepticism; it is directed against the very ideas of rule following and meaning. In the first instance, at stake is only my having meant plus by '+' *so far*. It must be assumed that at present I mean plus by '+,' since otherwise the paradox cannot even be formulated. However, if there are no facts constituting my having meant plus in the past, then there cannot be facts constituting my meaning plus at present. The paradox concerns the phenomenon of a speaker meaning something by *e* – *speaker meaning* – rather than the *lexical* or *literal* meaning of *e* in a shared language. But even if one rejects the Gricean project of reducing literal to speaker meaning, there *could not be* such a thing as literal meaning unless members of a linguistic community could, individually, mean something by their utterances. Finally, the threat extends beyond the meaning of linguistic expressions to the 'content' of thinking, i.e., to what subjects believe, desire, etc. If nothing constitutes S meaning *plus* by '+' in saying '$7+5=12$,' then nothing constitutes S *judging* that 7 *plus* 5 *equals* 12 rather than that 7 *quus* 5 *equals* 12.

For Kripke, the only escape is an indirect 'skeptical solution.' No fact constitutes following or violating a rule in using e and hence meaning one thing rather than another by e. Fortunately, there is a surrogate. The correct answer to the question 'What is $68+57$?' is '125' and '5' is an incorrect answer in the following sense: the former is accepted and the latter is rejected by the linguistic community of which I am a member. Consequently, rule following, meaning and thought are *inherently social*: an individual outside of the context of a community can neither speak meaningfully, nor think, nor follow rules of other kinds. Communal approval is not a condition under which statements about what (semantic) rules a speaker or a community is following are *objectively true*, but it is a condition under which such statements can be *warrantedly asserted*.

Whatever the merits of communitarianism, however, it proffers no solution of the paradox, skeptical, or other. For one thing, one cannot rule out a priori that a whole community might misapply a rule. For another, if nothing constitutes my meaning plus by '+,' nothing constitutes the members of my community meaning approval rather than disapproval by saying e.g., 'Correct!.' An 'antirealist' semantics revolving around assertion conditions is just as vulnerable to nihilistic vagaries as a realist semantics based on truth conditions.

Nihilism about meaning and content is patently self-refuting. If it were correct, it could neither be articulated nor entertained. This does not absolve us, however, from pinpointing where precisely nihilism goes astray. The most popular avenue has been to invoke the idea of a *disposition*. Following (understanding and accepting) a rule is a potentiality. I mean plus by virtue of the fact that I would

have answered '125' to the question. But dispositionalism cannot do justice to the normative character of rules in general and meaning in particular. Dispositions can sustain predictions about what *will* occur, yet not statements about what *should* occur or what is *correct* (Waismann, 1965: Chapters 7, 18; Kripke, 1982: 22–37).

To say, for instance, that '125' is the correct answer is not to say that it is the one, which a computer or I are predisposed to give. Computers can malfunction and I might make a mistake. Rather, we judge by reference to the rule whether the computer has broken down, or whether I am inclined to give the *right* answer. If '+' is to mean plus in a language, then something must count as the correct answer, irrespective of what individual speakers are inclined to answer. After all, speakers do not just use words, they also misuse them. Even if *I* am to mean plus by '+,' irrespective of lexical meaning, something must count as the answer *I should proffer*, irrespective of my disposition. Otherwise, I could not make a mistake relative to my understanding, since the answer I actually give is the one I am disposed to give.

There have been four distinct reactions to Kripkenstein. The first is *reductionism*. It tries to account for normativity in purely descriptive terms acceptable to naturalism. The most popular avenue has been to modify dispositionalism. It insists that the correct answer is the one I am predisposed to give *under ideal conditions*. Thus one might characterize the semantically constitutive dispositions as those, which are not subject to interference like disease or malfunction, or as those which are in line with the biological function and hence, the evolutionary history of the pertinent cognitive system (Millikan, 1990). Yet no set of conditions, however, propitious to an individual's performance or crucial to the emergence of the pertinent cognitive system, can *guarantee* that an answer is correct. Unless, that is, conditions *count as ideal* only if they engender the *correct* answer. In that case, however, the explanation of what constitutes correctness is circular.

The second reaction harks back to Wittgenstein. The 'paradox' according to which 'no course of action could be determined by a rule' is based on a 'misunderstanding'; it shows not that the rule leaves its applications undetermined, as nihilism has it, but that "there is an understanding of the rule which is *not* an interpretation, but is exhibited in what we call 'obeying the rule' and 'going against it' in actual cases" (1953: Sections 202, 189). There is no potential 'gap' between a rule and its application. Rather, the relation between the two is internal, i.e., constitutive of the relata. *Plus* simply *is* the function that yields 125 for the arguments 68 and 57. And to understand 'plus' simply *is* to know that 125 is the correct answer (Baker and Hacker, 1984b; Glock, 1996: 323–329). This reaction faces a further skeptical question: What makes it the case that I am following the *plus* rule (internally related as it is to its applications), as opposed to the *quus* rule (Hattiangadi, 2007: 172–177). And it must meet that challenge without appeal either to mere communal dispositions or treating rules as mysterious platonic entities that somehow contain all of their infinitely many applications.

A third reaction may be capable of evading this challenge. It maintains that the paradox arises from a misguided reductionist project of specifying nonnormative, purely natural facts that rule following, meaning, and thinking consist in (McDowell, 1984). These phenomena are (rooted in) human practices, but they are *sui generis*. While they can be elucidated by pointing out their connection to other normative phenomena such as explanation and understanding, they cannot be reduced to phenomena of a more fundamental, natural kind.

Finally, there is the option of denying that the normativity of meaning is genuine in the first place. It has become increasingly popular, especially among naturalists trying to defuse the challenge posed by normativity. Drawing on recent work by Davidson and Chomsky, antinormativists have questioned received views about the connection between meaning and rules. The remainder of this article is devoted to the lively ensuing debate.

Dimensions of Semantic Normativity

Norms in the relevant sense differ from statements of mere regularities or natural laws in three interrelated respects.

First, they do not (merely) describe or explain, but set standards, in particular, standards against which behavior can be assessed as correct or incorrect. If planets turn out to follow paths other than elliptical ones, it is Kepler's Laws rather than the movement of the planets which needs revision. By contrast, if I drive on the left-hand side it is my driving rather than the Traffic code, which is at fault. The direction of fit is from world (action) to mind (norm).

Second, although rule following presupposes a regularity in behavior, there is a difference between rule-guided and merely regular behavior. If an agent follows a rule in Φ-ing, the rule must be part of her reason for Φ-ing, and more specifically, for Φ-ing in a particular manner. Rule following is, therefore, a type of intentional or goal-directed behavior.

Third, 'to follow a rule' is an achievement verb. There is a difference between an agent actually following a rule and her merely believing that she does.

The first feature is equally present in desires, and all three are shared by commands, orders, and requests. A fourth feature sets norms apart, namely that they are inherently general. Although norms are commonly restricted to certain types of subject and types of situation (context sensitive), they govern an unlimited multiplicity of occasions (occasion neutral).

Finally, there is a difference between a rule and its linguistic expression – a rule formulation. A rule need not be expressed linguistically, and one and the same rule may be expressed in different ways. In short, a norm is a general standard that provides a reason for action and against which actions can be assessed as correct or incorrect.

Within the debate over the 'normativity of meaning,' we must distinguish various normativity claims. Three of them concern linguistic meaning.

Bare Normativity of Meaning

e is meaningful ⇒ [conceptually entails] there are conditions for the correct use of *e*.

If an expression *e* is meaningful, then there must be conditions for its correct application. "Suppose the expression 'green' means *green*. It follows immediately that the expression 'green' applies correctly only to these things (the green ones) and not to those (the non-greens). The fact that the expression means something implies, that is, a whole set of *normative* truths about my behaviour with that expression: namely, that my use of it is correct in application to certain objects and not in application to others" (Boghossian, 1989: 148).

Rule-Based Normativity of Meaning

e is meaningful ⇒ there are rules for the use of *e*.

Historically 'norm' means roughly the same as *rule*. However, 'normativity' has also been employed more widely, for all phenomena that can be assessed for *correctness* according to a *standard*, whether or not this involves rules, understood as standards guiding action. According to rule-based normativity of meaning (RNM), meaning requires rules of use, since the correctness conditions of bare normativity of meaning (BNM) are laid down by such rules.

Prescriptive Normativity of Meaning

e is meaningful ⇒ there are prescriptions for *e*'s use.

Prescriptive normativity of meaning (PNM) is stronger than RNM, since not all rules prescribe what one ought to do.

In contemporary debates, normativity claims that concern the meaning of linguistic expressions are intertwined with those that concern the *conten*t – the concepts or thoughts – expressed by their employment. One of them is Dummett's (1981: 300) proposal that the concept of assertion entails the existence of certain rules, notably that an assertion should aim to be true.

Normativity of Content: Assertion

a asserts that *p* ⇒ there are rules for asserting that *p*.

The other concerns the content of beliefs rather than assertoric utterances.

Normativity of Content: Belief

a believes that *p* ⇒ there are rules for asserting that *p*.

Accordingly, our general topic divides as follows (**Table 1**):

Table 1 Aspects of semantic normativity

Finally, the normativity of meaning is connected to the issue whether meaning is a matter of conventions, i.e., of rules that are arbitrary and shared between members of a speech community.

Conventionality of Meaning

e is meaningful ⇒ there are conventions for using *e*.

Normativity, Truth, and Meaning (BNM)

Most antinormativists grant BNM. That an expression has a specific meaning implies that there are conditions for its *correct* use. At the same time, they confront normativism with a *dilemma*: either these semantic principles are *not really normative*; or they are *not in fact constitutive of meaning*, i.e., they do not follow from an expression being meaningful (Glüer and Wikforss, 2009). BNM is supposed to fall under the first horn; RNM and especially PNM under the second.

A popular way of capturing the idea that general terms require conditions of correct application is

$$(\mathrm{BNM}_1)\ e \text{ means } F \Rightarrow \forall x\ (\text{it is correct to apply } e \text{ to } x \leftrightarrow x \text{ is } f)$$

(where '*e*' is a general term, '*F*' gives its meaning, and '*f*' is that feature in virtue of which *e* applies to an object *x*). The consequent of BNM_1 provides the scheme for a 'semantic principle' of the kind employed in formal semantics. The first antinormativist objection runs: 'correct' in (BNM_1) is not genuinely normative, since it is simply a place holder for 'true'; 'it is correct to apply *e* to *x*,' in other words, boils down to *e holds true of x* (Boghossian, 2005; Hattiangadi, 2007: 51–61).

One cannot counter this objection by pointing out that semantic principles *give rise* to norms. The same holds for descriptive statements. For one thing, they can give rise to technical norms or rules, given additional premises of a normative kind. That compact fluorescent lamps consume less energy than standard lightbulbs may give rise to norms requiring the fitting of compact fluorescent lamps, given a norm requiring energy savings. For another, one can criticize statements and actions by reference to empirical statements no less than by reference to semantic principles.

At the same time, by dint of its connection with truth, holding true is what Parfitt (1997) calls 'normatively relevant.' A proposition being true (or a predicate holding true of something) can have implications for what it is correct to believe or do, implications that depend on fundamental features of human thought and action rather than specific normative premises. We need to modify, i.e., 'correct' our beliefs and activities in the light of what is the case, of things being thus-and-so. This, in turn, reflects the fact that how things is essential to how we should pursue our goals (Horwich, 1998: 44–46; Glock, 2003: 131–136).

Furthermore, the antinormativist objection assumes that semantic norms would have to be norms of truth, norms to the effect that one ought to think and state what is true. That assumption has also been accepted by most normativists (e.g., Blackburn, 1984: 281–282). But the contrast between correct and incorrect applies to language in a variety of ways, and their connection to the notion of meaning differs. In particular, one

can use a word meaningfully, in a sentence with a sense that expresses a thought, without that thought being *either* true *or* justified. This difference between truth and meaning emerges when we consider different types of mistakes that people can make in using words. First, in the run up to a by-election to the House of Commons a candidate once said,

1. I know that I cannot win this seat.

There was nothing wrong with (1) either linguistically or factually. Yet she made a dreadful mistake, because it is not politic to admit to such dim prospects. Next consider Tony Blair's statement in the House of Commons,

2. Iraq is capable of deploying weapons of mass destruction within 45 min of an order by Saddam Hussein.

There is nothing wrong linguistically with (2), yet it is both unjustified and false. Now consider George W. Bush's

3. You teach a child to read, and he or her will be able to pass a literacy test.

Here we are confronted with a linguistic mistake. But it is of a syntactic rather than semantic kind. In fact, once we correct for that error, (3) is analytic, at least on a certain understanding of 'teach' and 'literacy.' In spite of involving a solecism, therefore, this example shows Bush at the very height of his semantic powers. That is more than can be said of

4. I am mindful not only of preserving executive powers for myself, but for my predecessors as well.

Here Bush's travails are semantic. The statement (4) betokens not lack of factual knowledge, but an insufficient grasp of the meaning of at least one of the two terms 'preserving' and 'predecessors.'

There is a fundamental contrast between saying something false or unjustified – as in (2) – and saying something meaningless – as in (4). Some uses of words are mistaken *solely* because of *what these words mean*, irrespective of any other facts, syntactic rules, or social expectations. Conversely, one can apply a word in a way, which is *semantically correct* – based on a proper understanding of its meaning – without applying it correctly in the sense of saying something *true*, namely if one errs about pertinent facts (but see Whiting, 2013).

The meaning of *e* is determined by a rule, which specifies the conditions *f* under which *e* applies to *x*. Whether a speaker S violates that rule depends not on whether *x* actually satisfies *f* – that is a matter of fact/knowledge rather than meaning/understanding; it depends instead on whether S applies or withholds *e* according to whether *x* satisfies *f*.

For Wittgenstein, whether a sentence expresses a rule does not depend on its linguistic form, but on whether it has a normative function, either in general or on a given occasion of utterance. Rule formulations need not contain a deontic verb. And formulations of linguistic rules need not be metalinguistic statements that mention the expressions for which they provide a rule. By these lights, all explanations of meaning are semantic rules.

5. The term 'drake' means *male duck*.
6. A drake is a male duck.

Both (5) and (6) are standardly used to explain what the term 'drake' means. Because they function as explanations, they also have a normative role: we can criticize and justify our use of 'drake' by reference to them.

Facts of Use, Correctness, and Normativity (BNM)

Focusing on the explanations we actually employ in teaching, justifying, and criticizing the use of expressions (dictionary explanations included) avoids serious distortions (Glock, 2003: Chapter 5). If the normativity of meaning is instead discussed by reference to formal semantic principles the latter must at least be suitable as explanations of meaning. For 'drake,' such a principle might run:

7. It is correct to apply 'drake' to *x* iff *x* is a male duck.

Antinormativists concede

$$(\mathrm{BNM}_2)\ \text{'drake' means what it does} \Rightarrow (7)$$

At the same time they deny that (7) has a bona fide normative status, a first objection is that the alleged semantic norms boil down to mere 'descriptive facts' concerning linguistic behavior (Glüer, 2001). But we must distinguish between (7), which standardly expresses a norm, and something like

8. In English, it is correct to apply 'drake' to an object *x* iff *x* is a male duck.

(8) be used to invoke a norm within the Anglophone community. Yet it can also be used as an empirical 'norm-proposition' to the effect that this community follows that norm (von Wright, 1963: viii, 108). In that capacity, (8) states a fact about the behavior of Anglophones. It does so, however, only because the Anglophone speech community accepts a certain norm, a standard for the correct use of 'drake.' That is to say, (8) is a true factual statement about a norm precisely because (7) expresses a norm.

One could insist, however, that (8) overstates the normativist case (see Davidson, 2005: 109–112). All we really have is

9. Among a certain population, most people tend to apply 'drake' to an object *x* only if *x* is a male duck.

(9) is indeed bereft of normative implications. But there is more to our practice than statistical regularity. We not only tend to apply 'drake' to male ducks. We also explain the term as a label for male ducks, and we criticize and justify our use of the term by reference to statements like (5)–(7). Applying 'drake' to *x* on the grounds that *x* is a male duck or a female fox counts as (semantically) incorrect, a sign of deviant understanding.

It is widely assumed that notions like 'correct' or 'mistaken' are normative (Blackburn, 1984: 286–287), even among those skeptical about the normativity of meaning (Boghossian, 2003: 35; Fodor, 2008: 205). A second antinormativist objection questions this assumption.

A serviceable explanation of correctness runs as follows: (COR) *x* is correct iff *x* is in accordance with an acknowledged standard.

This standard may be part of a specific system of evaluation appropriate to *x*, as when we speak of correct academic

dress. Or it may be a general standard expressing certain demands, e.g., on prudential or moral conduct. Either way, there must be a standard specifying conditions under which *x* counts as correct.

At this juncture it is tempting to argue that calling *x* correct is merely to state that it satisfies these conditions, and hence that the concept has no normative implications after all. However, in characterizing *x* as correct we do not just ascribe to *x* the *features* specified in the relevant standard. We also characterize *x* as *meeting a standard* of positive evaluation. The term 'correct' is not purely descriptive or factual, but *evaluative*. What is more, unlike other evaluative terms, e.g., 'good,' it carries the further implication that failure to meet this standard is not just undesirable, but provides grounds for *intervention*. After all, the verb 'to correct' means to set right, rectify, or amend. Applying *terms used in the standard* may be purely descriptive, but applying the term 'correct' is *not*. And to call something incorrect is not only to evaluate it negatively; if something is incorrect, then one has grounds for *correcting* it. No normative force attaches to the statement that *x* is not wearing a cap and gown. But given the standards of correct academic dress, not wearing them on an official occasion constitutes being dressed incorrectly, and is therefore liable to be corrected.

This lesson carries over to semantic normativity. According to antinormativists, "To say that some use of a term is 'correct' is … merely to describe it in a certain way—in light of the norm or standard set by the meaning of the term" (Hattiangadi, 2006: 225). To categorize something by reference to the defining features of a drake has no normative implications per se. To deny that an object *x* possesses the defining features of a drake, for instance, is not to characterize *x* as fit for correction. At the same time, the 'norm or standard set by the meaning' of 'drake' makes reference to these features, just as the standard for correct academic dress makes reference to cap and gown. And to categorize applying 'drake' to *x* on the grounds that *x* is a female fox as incorrect has direct normative implications, since it characterizes that application as fit for correction.

More generally, to assess an assertion or belief as false is to present it as fit for epistemic correction. Equally, to assess an utterance as meaningless, nonsensical or a malapropism is to present it as fit for semantic correction. To be sure, on particular occasions a speaker may aim to make false assertions, to commit linguistic mistakes, or to utter nonsense. In that case, what she does may be correct relative to a different standard – a prudential or moral one, for example. If that standard is more important in the situation, what she does may also be correct in an 'all things considered' sense. But this does not detract from the fact that she is violating semantic or epistemic norms. In semantic principles like (7), 'correct' is not used in the all things considered sense. Conversely, the general norms of reason presupposed in that usage are not constitutive of the meaning of specific terms (although they feature in the semantic norms governing terms like 'reasonable' or 'rational').

Meaning, Rules, and Prescriptions (RNM, PNM)

Even if (7) has a normative status vis-à-vis linguistic performances, RNM may be wrong in portraying it as a genuine rule (Stainton, 1996: 139–142; Glüer and Pagin, 1999). After all, it does not oblige or even entreat us to apply the term 'drake' to an object in a particular situation.

However, there is also the 'definitory aspect of rules' (Baker and Hacker, 1984a: 259). Some rules do not prescribe a certain form of behavior, but instead lay down what a thing must be like to satisfy a certain description. Prime examples are the beloved EU norms concerning, for example, what qualifies as chocolate or the rules of games like chess. These norms lay down *what counts as* chocolate or as castling, without requesting anyone to produce or buy chocolate, or to castle.

This point is connected to a well-known distinction between *regulative* and *constitutive* rules (Searle, 1969). Regulative rules advise one on how to pursue in an optimal fashion an activity that can be specified independently of the rule. Constitutive rules are partly definitive of the activity in question. What goes on at dinner parties can be described as eating independently of the rules of etiquette. By contrast, what goes on when people move certain pieces across a board cannot be described as castling, checking, mating, or, more generally, as playing chess, independently of rules like 'The king cannot castle out of a check' or "The king is mate if it is in check in such a way that no move will remove it from being in check." This contrasts with a regulative rule of chess like 'Do not relinquish control of the center.' Even someone who disregards all these regulative rules does not cease to play chess, he will just play chess badly.

Constitutive rules – especially those of legal systems and games – make up a paradigmatic type of rule. But do semantic principles qualify? It might be thought that someone who violates a constitutive rule of chess is no longer playing chess, while someone who violates the alleged constitutive rules of English is still speaking English. This qualm is dubious on both grounds. It is implausible to insist that a game involving a single incorrect move no longer counts as chess. Conversely, although someone who commits a mistake may still speak English, the *mistake itself* does not count as English. It is quite common to react to a serious mistake by protesting 'That's not English.' And someone who commits many such mistakes can be said not to be speaking English. What is true is that the margin of tolerance is greater and less well defined in the case of natural languages than in the case of chess. There is a simple though important reason for this: the constitutive rules of natural languages do not form a precise and canonized system.

A final worry is that semantic principles lack the action-guiding force of genuine rules. The latter, it is often maintained, have to be deontic statements about what one *ought to do* (Hattiangadi, 2006; Boghossian, 2003). As we have seen, however, by laying down conditions under which terms of a language can be applied, semantic principles *also* lay down conditions under which certain utterances are *correct*. For instance, by specifying what counts as a drake, explanations like (5) or (6) *also lay down* what counts as using the term 'drake' in a correct, in the sense of meaningful, way – a point which comes out in statements like (7). Such statements support *prohibitions*. We can justify as

10. You ought not to apply 'drake' to a female fox or a male duck.

by reference to (7). More generally, we often say

11. You shouldn't call that …, because it's not ….

Finally, even among regulative rules, there are not just *prescriptive* 'norms of obligation' (von Wright, 1963) or 'mandatory norms' (Raz, 1978) of the form

(MN) x ought to ϕ in Condition C

There are also 'permissive norms' of the form

(PN) x is entitled to ϕ in condition C

Entitlements presuppose a background of prohibitions. Such a background is provided by injunctions like (10) and (11), even though the immediate sanctions for violating them may be confined to correction and ridicule. Some theorists have suggested that permissions reduce to obligations, either because they are the mere absence of obligations or because they are obligations on others not to interfere. The second claim does not pose a threat to regarding permissions as rules, since it merely relocates their normative trajectory. And the first ignores two points. We can invoke permissive norms in defense of Φ-ing, and this goes beyond merely averring that there is no proscription on Φ-ing. Furthermore, we can adduce these norms to explain our Φ-ing even in the absence of any challenge.

It is common to employ explanations like (5)–(6) as permissive norms. I can appeal to a definition like (5) in defending or explaining my use of 'drake.' If challenged why I call a male duck a drake I can defend myself by saying that 'drake' means *male duck* (Glock, 2005: 234–235; Whiting, 2009). Furthermore, explanations of meaning also function as transformation or inference rules. Thus Wittgenstein urged that ostensive definitions are substitution rules. 'This ☞ is red,' for instance, entitles one to pass from 'My bike has this ☞ color' to 'My bike is red' (1974: 88–91, 202).

The idea that transformation rules are constitutive of meaning was developed by inferential role semantics (Sellars, 1963; Brandom, 1994). The statement (5) licenses transitions between empirical propositions, e.g., from 'This creature is a male duck' to 'This creature is a drake' and vice versa. In other words, we can appeal to (5) in support of an inference like,

12. Donald is a male duck, therefore Donald is a drake.

And this inference is licensed by the semantic rule alone, independently of facts.

A final criticism of PNM revolves around the idea that genuine norms must be or imply *categorical imperatives*. Unlike merely hypothetical imperatives, such imperatives are independent of any desires or goals that the addressee might have. Now, a speaker can violate semantic prohibitions like (10) by lying. Yet this only shows that they are genuine rules, something one can obey or fail to obey. What disqualifies semantic prohibitions from being categorical is that they can be overridden by other rules *in certain situations*. Kant notwithstanding, however, this arguably holds for *all* imperatives.

In any event, that an imperative is merely hypothetical does *not* entail that it lacks normative force altogether. The opposite view is fueled by the conviction that a genuine 'ought' must indicate an 'all things considered' obligation. Yet in our normative discourse we recognize the possibility of bona fide yet prima facie or *pro tanto* obligations. We frequently engage in deliberations like,

13. On the one hand I ought to Φ, on the other I should Ψ in cases in which we cannot both Φ and Ψ.

RNM would be threatened if injunctions like (10) could be overridden simply by 'a desire to lie or deceive' (Hattiangadi, 2006: 231–232; Glüer and Wikforss, 2009: 2). But lying is something one ought not to do, since it undermines the trust essential to human communication and interaction (Glock, 2005: 237–238). Although the prohibition to lie can be overridden by more pressing obligations in certain situations, its validity does *not* depend on any desire or decision on the speaker's part. One is not entitled to lie simply because one feels like it.

Normativity of Content (NCA, NCB)

The issue of lying is also pertinent to normativity of content: assertion (NCA). A rule that is often regarded as implied by the possibility of assertion

14. $\forall p$ (one ought to assert that p only if p)

But to assert what one believes or knows to be false does not straightforwardly undermine the very possibility of assertion (Boghossian, 2003: 39). Otherwise lies could not be assertions. On the other hand, a norm can be constitutive of a practice in spite of being occasionally violated. From the fact that something can *sometimes* be the case, it does not follow that it can *always* be the case.

In this vein, Aquinas and Kant contended that a practice of uniformly insincere assertions cannot be consistently conceived. One possible rationale runs as follows. A speaker can only assert something by uttering 'p' if she *presents herself* as thereby expressing something she believes. Statements like 'p, but I do not believe that p' or 'I assert that p, but I do not believe that p' are self-defeating. Furthermore, spare a thought for a speaker who persistently says that p without believing that p. If this were common knowledge, i.e., if it were known to everyone and also known to everyone – including the speaker – that it was known to everyone, her utterances would no longer count as assertions. And if this scenario extended to all speakers, the practice of assertion would collapse.

Dummett has further maintained that there is a convention whereby in making an assertion speakers aim at truth, just as there is a convention according to which in making a move in chess players aim at the stipulated point of the game, e.g., checkmating in chess (1981: 296–298). But one must not take the analogy between a language and a game too far. Although we complain about insincere assertions, our complaint makes no reference to the constitutive rules of a specific language. We do not say "In French one doesn't lie, whereas in English it's ok", as we might say, "In draughts, one doesn't mate, whereas in chess one does" (Schroeder, 1998: Section 21).

There is a crucial difference between NCA and normativity of content: belief (NCB). The question 'Should I believe the truth' cannot even arise, whereas the question 'Should I tell the truth' often does. If the person accepts that a belief is false, she thereby ceases to have the belief. But does this mark a special kind of normativity or instead

cast doubt on NCB (see Boghossian, 2003; Zalabardo, 2013)?

According to a traditional principle, ought implies can. It must be within the agent's power to do what she ought to do, but *also* within her power to decide *against* doing it. But it is not within my power to decide to believe something that I take to be false (Williams, 1973: Chapter 9; cp McHugh, 2012). Whereas I have an obligation to refrain from asserting what I take to be false, I cannot have this kind of obligation vis-à-vis my beliefs.

Admittedly, NCB can be taken in a weaker sense. That we ought to Φ can simply mean that we can be held *responsible* for not Φ-ing. This notion applies beyond actions that one can refrain from performing. Under certain circumstances we can be held responsible for our character traits and moods, even though these are not actions that we can deliberately perform or refrain from performing. In a similar fashion, we can be held responsible for our beliefs. But this responsibility can only underpin 'subjective' norms such as

15. ∀p (one ought to believe that p only if it is reasonable to believe that p)

not 'objective' norms. For we cannot be held responsible for believing something that is false, provided our belief is reasonable, e.g., based on convincing evidence. Whereas truth is decided by what is the case, the responsibility we have for our beliefs reaches no further than the best available reasons we have for them. A belief must allow of being 'objectively' assessed for truth. But only the way we heed the reasons for or against a belief is subject to the type of action-guiding rules that apply to assertion.

Meaning and Convention (CM)

For present purposes, conventions are social rules that are arbitrary (Glock, 2010). Expressions do not have an intrinsic meaning. Rather, what they mean is determined by how they are used. As a result, what a linguistic expression means is arbitrary in the following respects:

- In different languages, different words are used to mean one and the same thing.
- In some languages the same linguistic form is used to mean different things (e.g., 'link' in English and German).
- We could, in principle, use words to mean something different from what they in fact mean.

The debate between individualists and communitarians turns on whether arbitrary semantic principles must be shared between speaker and hearer, or, more generally, between the members of a linguistic community. Individualist opponents of the conventionality of meaning (CM) argue as follows: if the meaning of an expression *e* in a language L is determined or constituted by the use speakers make of *e*, the meaning of *e* cannot at the same time prescribe a certain use to the speakers of L. Accordingly, the idea that the use of *e* is governed by shared lexical norms is a lapse into the Platonist picture according to which "the meanings of words are magically independent of the speaker's intentions" (Davidson, 1990: 310).

But one must distinguish between the use an individual speaker makes of *e*, and the use that the linguistic community makes of it. *Communal* use may *constitute* meaning, while *individual* use is *responsible* to it. From this perspective, the existence of lexical norms and their independence from the utterances and intentions of individual speakers is no more mysterious than the existence of legal norms and their independence from the acts and motives of individual agents.

However, while an appeal to conventions can explain legal norms, by pain of regress it cannot explain language in the same manner, because articulating conventions presupposes language (Russell, 1921: 190; Davidson, 1984: 280). Nevertheless, given that there is a difference between a rule and its linguistic formulation, there can be *implicit* rules that guide our communicative behavior without having been enunciated or being consciously consulted (Brandom, 1994: Chapter 1; Glock, 2003: 92–95, 247–248). Language probably arose when cooperative activities put a premium on the intentional and regular use of signals, a communicative practice that gradually became subject to normative reactions and sanctions (Tomasello, 2008). But it remains to be shown how this process can be conceptualized and explained without assuming that the subjects possess mental faculties of a kind that in turn presuppose language.

Turning from the phylogenesis of language to its nature, individualists standardly grant that we tend to speak as others do, while insisting that this is for extrinsic social reasons that are inessential to linguistic communication. Knowledge of shared rules is neither necessary nor sufficient for successful linguistic communication. For malapropisms, spoonerisms, and similar infelicities are not merely common, but commonly understood (Davidson, 2005: Chapters 8–9). In appropriate circumstances, we have no difficulty in understanding Mrs Malaprop's remark "A nice derangement of epitaphs" as meaning "a nice arrangement of epithets." The question remains whether such understanding does not rely on a background of shared conventions after all. For one thing, from the fact that people can deviate sometimes, it does not follow that they could always deviate. It is difficult to see how we might all be constantly committing malapropisms without communication breaking down. For another, while we are often, albeit by no means always, capable of understanding semantic infelicities, this may be limited to recognizable and, in some way, intelligible deviations from a shared norm. Finally, in the case of malapropisms, what we understand is what speakers *meant to say*, not what *they actually said* or the literal meaning of the expressions they uttered.

Individualists point out that communication can succeed even between individuals who do not share a language, even passively. In interactions with foreigners, we sometimes communicate by way of facial expressions, gestures, and intonation. The moot question is whether there is or could be communication by *language* without semantic conventions, i.e., whether linguistic communication could be based solely on a mutual process of ingenious mutual interpretation. Our concept of language is not sufficiently clear cut to provide a definite answer. But verbal communication without conventions, and hence without literal meaning, would definitely be incapable of expressing the fine-grained thoughts we can express in natural languages. This is crucial to the unique

role such languages play for human beings. They allow us to express and communicate complex thoughts even to strangers, people of whose beliefs, intentions, and desires we are largely ignorant. Semantic conventions may not be part of the essence of linguistic communication, yet nevertheless required by the anthropological function language has for our species of social primates. Finally, the debate about shared intentionality (Gilbert, 1996) suggests that obligations can arise from the structure of a practice that we participate in. By these lights, an obligation to speak as others do can result from our participation in the practice of linguistic communication, a practice we engage in willy-nilly, as a result of enculturation.

This article is reproduced from the previous edition, volume 14, pp. 9435–9442, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

In many areas of application, response variables are modeled in terms of one or more covariates that are not directly observable. Instead, substitute variables that can be observed are used in place of the covariates of interest in the model. Because these substitute variables measure the original covariates with error, we use the term *measurement error models* to describe those models. In the simple additive case, measurement error has the effect of masking or *attenuating* the relationship between the response variable and the covariate measured with error. A correction for attenuation can be carried out only if replicate observations are available, or if information about the measurement error can be obtained from other sources. Results derived for the simple case can be extended, but not in a straightforward manner, to the multivariate regression case. Measurement error problems in a nonlinear setting have also been addressed in recent years. Logistic regression models with measurement error in one or more of the covariates have received much attention since the 1980s.

The term *measurement error model* is used to denote a regression model, either linear or nonlinear, where at least one of the covariates or predictors is observed with error. If x_j denotes the value of the covariate for the ith sample unit, then x_i is unobserved and we observe instead $X_i = f(x_i, u_i)$, where u_i is known as the *measurement error*. The observed (or *indicator*) variable X_i is assumed to be associated to the unobserved (or *latent*) variable x_i via the function f; the form of this association defines the different types of measurement error models described in the literature. For a comprehensive bibliography on this literature, see Fuller (1987) and Carroll (1995).

In the simple additive measurement error model, measurement error has the effect of obscuring the relationship between the response variable and the covariate that is measured with error. This effect is sometimes known as *attenuation*, as in the linear regression case, the ordinary least squares estimator of the regression coefficient associated to the variable that is measured with error is biased towards zero (e.g., Fuller, 1987).

The next section describes the effect of additive measurement error in the simple regression case, and notes the relationship between this topic and those in other entries. Subsequent sections describe extensions to the multivariate and nonlinear regression cases. The article ends with a brief historical overview of the development of measurement error models.

Simple Linear Regression and Measurement Error

The simple linear regression model (*see* Linear Hypothesis: Regression (Basics)) is given by

$$Y_i = \beta_0 + \beta_1 x_i + e_i \qquad [1]$$

where Y_i is the response observed for the ith sample item, x_i is the explanatory variable (or covariate) measured for the ith sample item, β_0 and β_1 are unknown regression coefficients, and e_i is random error typically assumed to be distributed as a normal random variable with mean 0 and σ_e^2. Here we talk about *functional models* when the explanatory variable x is assumed to be a fixed value, and about *structural models* when instead x is assumed to be a random draw from some distribution. Typically, we choose $x \sim N(\mu_x, \sigma_x^2)$ (e.g., Fuller, 1987). [Carroll (1995), however, makes a different distinction between functional and structural models. They refer to *functional modeling* when the variable x is either fixed or random but minimal assumptions are made about its distribution, and to *structural modeling* when a parametric form is chosen for the distribution of x. Carroll (1995) argues that when a consistent parameter estimate under the structural model formulation can be found, it tends to be robust to misspecification of the distribution of x.]

It is well known that the ordinary least squares estimator (*see* Linear Hypothesis: Regression (Basics)) of β_1

$$\widehat{\beta}_1 = \frac{\sum_{i=1}^{n}(Y_i - \overline{Y})(x_i - \overline{x})}{\sum_{i=1}^{n}(x_i - \overline{x})^2} \qquad [2]$$

is unbiased and has smallest variance among linear unbiased estimators. If $x \sim N(\mu_x, \sigma_x^2)$ and $Cov(x, e) = 0$, then the estimator $\widehat{\beta}_1$ in (2) is the maximum likelihood estimator of β_1 (*see* Estimation: Point and Interval).

Models for Measurement Error

Suppose now that we cannot observe the explanatory variable x_i directly. Instead, we observe the *manifest* or *indicator* variable X_i which is a noisy measurement of x_i. We distinguish two different types of measurement error models depending on the relationship between X_i and x_i:

1. Error models, discussed in this entry, where we model the distribution of X given x.
2. Regression calibration models, where the distribution of x given X is of interest.

Within the class of error models, we distinguish two variants: *classical additive error models*, and *error calibration models*. The *classical additive error model* establishes that the observed variable X is an unbiased measure of x. That is

$$X = x + u \qquad [3]$$

where $u \sim (0, \sigma_u^2)$. As an example, consider the problem of estimating the relationship between serum cholesterol levels and usual intake of saturated fat for a sample of individuals. Suppose further that intake of cholesterol for an individual is measured by observing the individual's intake over a randomly chosen 24-hour period. Because daily nutrient intake varies from day to day for an individual, the intake measured on any one day is a noisy measurement of the individual's usual or habitual intake of the nutrient.

We talk about *error calibration models* when the observed variable is a *biased* measurement of the variable of interest. In this case, we use a regression model to associate the two variables.

$$X = \alpha_0 \alpha_1 x + u \qquad [4]$$

where as before, $E(u) = 0$, but now $E(X) = \alpha_0 + \alpha_1 x$. As an example, consider the problem of assessing the habitual daily alcohol consumption for a sample of individuals. Typically, individuals in the sample are asked to record their alcohol consumption over a short period, for example over a week. The mean of the observed alcohol intakes over the seven days cannot be assumed to be an unbiased estimator of the usual daily alcohol consumption, as there is evidence (see Freedman et al., 1991; Carroll, 1995) that individuals tend to under-report the amount of alcohol they drink. Suppose in addition that the under-reporting is not correlated with alcohol consumption. In this case, the measurement X is biased for x and must be corrected. If information about relationship (4) is available, the measurement X can be *calibrated* by using $\alpha_1^{-1}(X - \alpha_0)$.

We briefly discuss *regression calibration models* later in this article.

The Effect of Measurement Error

Consider the simple example of a linear regression with additive measurement error in the covariate, as in expressions (1) and (3). Further, assume that the measurement error is independent of the true measurements x and of the errors e. If $X = x + u, x \sim (\mu_x, \sigma_x^2)$ and $u \sim (0, \sigma_u^2)$ then the regression coefficient estimated using the noisy measurements is biased towards zero. If $\widehat{\gamma}_1$ is the estimated regression coefficient obtained from using X in the regression equation, then

$$E(\widehat{\gamma}_1) = \lambda \beta_1 \qquad [5]$$

where β_1 is the regression coefficient associated to x and λ is called a *reliability ratio* (e.g., Fuller, 1987, Sect. 1.1; Carroll, 1995, Sect. 2.2.1), computed as

$$\lambda = \frac{\sigma_x^2}{\sigma_x^2 + \sigma_u^2} \qquad [6]$$

Clearly, $\lambda < 1$, and approaches 1 as the variance of the measurement error goes to zero. Therefore, ordinary least squares estimation in the model with X instead of x produces an estimator of the regression coefficient that is biased towards zero, or is *attenuated*.

Measurement error has in addition an effect on the variability of points around the estimated regression line. Note that under model (1) with measurement error as in (3),

$$\mathrm{var}(Y|X) = \sigma_e^2 + \frac{\beta_1^2 \sigma_u^2 \sigma_x^2}{\sigma_x^2 + \sigma_u^2} \qquad [7]$$

Thus measurement error has the effect of increasing the noise about the regression line (Carroll, 1995).

A simple simulated example

To illustrate the effect of measurement error on regression estimation, we constructed 10 responses $Y = \beta_0 + \beta_1 x + e$, where $\beta_0 = 0$, $\beta_1 = 2$, $e \sim N(0, 1)$, and $x \sim N(1, 1)$. We then constructed a noisy measurement of x by adding measurement error u where $u \sim N(0, 3)$. We fitted two simple linear regression models, using x and using X as the covariate in the model. The data, together with the two fitted regression lines are shown in Figure 1. In the figure, the dark dots represent the true measurements, while the diamonds represent the noisy measurements. Note that the regression line fitted to the noisy data is attenuated towards zero. In fact, in this simulated example, the true attenuation coefficient or reliability ratio is only $\frac{1}{4}$. Attenuation of the slope is greatly dependent on the simple additive error model. In other cases, the ordinary least squares estimator of the regression coefficient may *overestimate* the true slope. Consider, for example, the case where X is a *biased* measurement of x, and in addition, the measurement error is correlated with the equation error. That is, X is as in eqn [4] and Corr $(e, u) = \rho_{eu}$. It can be shown that

$$E\{\widehat{\gamma}_1\} = \frac{\beta_1^2 \alpha_1 \sigma_x^2 + \rho_{eu} \sigma_e \sigma_u}{\alpha_1^2 \sigma_x^2 + \sigma_u^2} \qquad [8]$$

where, as in eqn [5], $\widehat{\gamma}_1$ denotes the estimated regression coefficient obtained by using X in the model, and β_1 is the true

Figure 1 Simulated example. Black circles represent observations without measurement error. Diamonds represent the observations subject to measurement error in the covariate. The steeper line is the fitted regression line in the absence of measurement error, while the flatter line shows the fitted regression line in the presence of measurement error.

slope. Notice that, depending on the values of α_1 and of ρ_{eu}, $\widehat{\gamma}_1$ may actually over-estimate β_1.

Multiple Linear Regression and Measurement Error

Extension of results presented in Section Simple Linear Regression and Measurement Error to the case of multiple predictors is not straightforward, even if only one of the predictors is subject to measurement error and the measurement error model is as in eqn [3].

Let

$$Y = \beta_0 + \beta_1 x + \beta_w' \mathbf{w} + e \qquad [9]$$

where now $\mathbf{w}$ is a $p \times 1$ vector of predictors that are measured without error, β_w is the vector of regression coefficients associated to $\mathbf{w}$, and x is measured with simple additive measurement error as in eqn [3]. Furthermore, let $\sigma^2_{x|w}$ denote the variance of the residuals in the regression of x on $\mathbf{w}$. If model (9) is fitted using X in place of x, it can be shown (e.g., Gleser et al., 1987) that, as in eqn [5], the estimated regression coefficient for X is $\widehat{\gamma}_1 = \lambda\beta_1$, where

$$\lambda = \frac{\sigma^2_{x|w}}{\sigma^2_{x|w} + \sigma^2_u}. \qquad [10]$$

Notice that when x and $\mathbf{w}$ are uncorrelated, λ in eqn [10] reduces to eqn [6]. Gleser et al. (1987) show that when one of the covariates is measured with error, the regression coefficients associated to $\mathbf{w}$ that are measured without error are also biased, unless x and $\mathbf{w}$ are uncorrelated.

If now $\mathbf{x}$ is a $q \times 1$ vector of covariates measured with error, and $\mathbf{w}$ is as above, then the ordinary least squares estimates have expectation.

$$E\begin{bmatrix}\widehat{\gamma}_x \\ \widehat{\gamma}_w\end{bmatrix} = \begin{bmatrix}\Sigma_{xx} + \Sigma_{uu} & \Sigma_{xw} \\ \Sigma_{wx} & \Sigma_{ww}\end{bmatrix}^{-1} \times \left\{\begin{bmatrix}\Sigma_{xx} & \Sigma_{xw} \\ \Sigma_{wx} & \Sigma_{ww}\end{bmatrix}\begin{bmatrix}\beta_x \\ \beta_w\end{bmatrix} + \begin{bmatrix}\Sigma_{ue} \\ 0\end{bmatrix}\right\}. \qquad [11]$$

The ordinary least squares estimate of the regression coefficients will be unbiased only when $\sum_{uu} = 0$ and $\sum_{ue} = 0$.

Estimation in Measurement Error Models

Consider first the simple model (1) with measurement error as in eqn [3]. Assume that $(x, e, u)' \sim N[(\mu_x, 0, 0)' diag(\sigma^2_x, \sigma^2_e, \sigma^2_u)]$, and suppose that σ^2_u is known. Under this model, the vector, $(\mathbf{Y}, \mathbf{X})$ is distributed as a bivariate normal vector, and therefore, the sample first- and second-order moments form a set of sufficient statistics for the parameters. Fuller (1987, Sect. 1.2.1) and Carroll (1995, Sect. 2.3.1) derive *method of moments* (*see* Estimation: Point and Interval) parameter estimates that can be obtained from a one-to-one mapping from the minimal sufficient statistics to the vector $(\widehat{\mu}_x, \widehat{\sigma}^2_x, \widehat{\beta}_0, \widehat{\beta}_1, \widehat{\sigma}^2_e)$. For example,

$$\begin{aligned}\widehat{\beta}_0 &= Y - \widehat{\beta}_1 \overline{X} \\ \widehat{\beta}_1 &= \left(s^2_x - \sigma^2_u\right)^{-1} s_{XY}\end{aligned} \qquad [12]$$

where $\overline{Y}$ and $\overline{X}$ are the sample means of Y and X, and s^2_X band s_{XY} are the sample variance of X and the sample covariance between X and Y, respectively. Fuller (1987) shows that when σ^2_u is known and as $n \to \infty$,

$$n^{\frac{1}{2}}\left[\left(\widehat{\beta}_0 - \beta_0\right), \left(\widehat{\beta}_1, \beta_1\right)\right]' \xrightarrow{\ell} N\left\{(0,0)'\mathbf{T}\right\} \qquad [13]$$

where $(\widehat{\beta}_0 - \beta_1)$ are as in (12) and $\mathbf{T}$ is a positive definite matrix (see Fuller, 1987, Sect. 1.2.2).

Suppose now that rather than assuming that σ^2_u is known, we consider the case where the *relative* sizes of the variances $\sigma_u^{-2}\sigma^2_e$ are known. We use δ to denote the ratio of variances. Under the assumption of normality of $(x, e, u)'$ as above, method of moments estimators for $(\beta_0, \beta_1, \sigma^2_u)$ are

$$\begin{aligned}\widehat{\beta}_0 &= \overline{Y} - \widehat{\beta}_1 \overline{X} \\ \widehat{\beta}_1 &= \frac{s^2_Y - \delta s^2_X + \left[\left(s^2_Y - \delta s^2_x\right)^2 + 4\delta s^2_{XY}\right]^{\frac{1}{2}}}{2 s_{XY}} \\ \widehat{\sigma}^2_u &= \frac{s^2_Y - \delta s^2_X + \left[\left(s^2_Y - \delta s^2_x\right)^2 + 4\delta s^2_{xY}\right]^{\frac{1}{2}}}{2\delta}\end{aligned} \qquad [14]$$

where for $\widehat{\sigma}^2_u$ we choose the smallest root of the quadratic expression above, so that $\widehat{\sigma}^2_u < s^2_X$. Fuller (1987, Theorem 1.3.1) shows that, for $\theta = (\beta_0, \beta_1, \sigma^2_u)'$, and $\widehat{\theta} = (\widehat{\beta}_0, \widehat{\beta}_1, \widehat{\sigma}^2_u)'$ (as given in eqn [14]), as $n \to \infty$

$$n^{\frac{1}{2}}\left(\widehat{\theta} - \theta\right) \xrightarrow{L} N\left(0, \mathbf{\Gamma}\right) \qquad [15]$$

for $\mathbf{\Gamma}$ a positive definite covariance matrix. Asymptotic normality of $(\widehat{\beta}_0, \widehat{\beta}_1)$ holds even if the distribution of x is not normal.

The estimators above can be extended to the case where a vector $\mathbf{x}$ is measured with error. While in the simple linear regression case results apply in the functional and in the structural model framework, in the multivariate case we must distinguish between models in which $\mathbf{x}$ is assumed to be random and those in which $\mathbf{x}$ is assumed to be fixed. We consider first the *structural model* set-up, where $\mathbf{x}$ is taken to be random. In this case, the maximum likelihood estimators of model parameters derived under the normal model can be shown to be consistent and asymptotically normal under a wide range of assumptions.

Let

$$\begin{aligned}Y &= \beta_0 + \mathrm{x}\beta_1 + e \\ X &= \mathrm{x} + \mathrm{u}\end{aligned} \qquad [16]$$

where

$$\begin{bmatrix}\mathrm{x} \\ \mathrm{e} \\ \mathrm{u}\end{bmatrix} \sim N\left(\begin{bmatrix}\mu_x \\ 0 \\ 0\end{bmatrix}, \begin{bmatrix}\Sigma_{xx} & 0 & 0 \\ 0 & \sigma^2_e & \Sigma_{eu} \\ 0 & \Sigma_{ue} & \Sigma_{uu}\end{bmatrix}\right) \qquad [17]$$

Here, $\sum_{uu}$ and $\sum_{eu}$ are known. The maximum likelihood estimators of (β_0, β_1) are

$$\begin{aligned}\widehat{\beta}_0 &= \overline{Y} - \overline{X}\widehat{\beta}_1 \\ \widehat{\beta}_1 &= \left(S_{XX} - \Sigma_{uu}\right)^{-1}\left(S_{XY} - \Sigma_{ue}\right)\end{aligned} \qquad [18]$$

where $\mathbf{S}_{XX}$ is the sample covariance matrix of $\mathbf{X}$ and $\mathbf{S}_{XY}$ is the covariance matrix of $\mathbf{X}$ and $\mathbf{Y}$. A modified maximum likelihood estimator of $(\beta_0, \beta\mathrm{a}_1)$ for the case where $\sum_{uu}$ and $\sum_{eu}$ are

unknown and must be estimated from the data is given by Fuller (1987, Sect. 2.2).

If the vector $\mathbf{x}$ is taken to be fixed, rather than random, the method of maximum likelihood fails to produce consistent estimators of the parameters in the model. This is because the vector of unknown model parameters (β_0, β_1, $\mathbf{x}_1$, $\mathbf{x}_2$, …, $\mathbf{x}_n$, $\sigma^2{}_e$) is n + 3-dimensional, but the sample size is only n. In this case, then, the number of parameters increases with sample size. Estimation of model parameters in these cases has been discussed by, for example, Morton (1981).

Consider now model (16) with assumptions as in (17), and suppose that we do not know $\sum_{uu}$ and $\sum_{eu}$ as above. Instead, let $\boldsymbol{\varepsilon} = (e, \mathbf{u})' \sim N\,(\mathbf{0}, \sum_{\varepsilon}\sum_{\varepsilon})$, where $\sum_{\varepsilon\varepsilon} = \boldsymbol{\Omega}_{\varepsilon\varepsilon}\,\sigma^2$, and $\boldsymbol{\Omega}_{\varepsilon\varepsilon}$ is known. In this case, the maximum likelihood estimators of β_1 and σ^2 are

$$\begin{aligned}\widehat{\beta}_1 &= \left(\overline{\mathrm{X}}'\overline{\mathrm{X}} - \widehat{\lambda}\Omega_{uu}\right)^{-1}\left(\overline{\mathrm{X}}'\overline{\mathrm{Y}} - \widehat{\lambda}\Omega_{ue}\right)\\ \widehat{\sigma}^2 &= (q+1)^{-1}\widehat{\lambda}\end{aligned} \qquad [19]$$

where $\overline{\mathrm{X}}'\overline{\mathrm{X}}$ and $\overline{\mathrm{X}}'\overline{\mathrm{Y}}$ are averages taken over the n sample observations, and $\widehat{\lambda}$ is the smallest root of $\left|\overline{Z}'\overline{Z} - \lambda\Omega_{\varepsilon\varepsilon}\right|$ with $\mathbf{Z} = (\mathbf{Y}, \mathbf{X})$. The estimator of β_1 is the same whether $\mathbf{x}$ is fixed or random. Under relatively mild assumptions, the estimator $\widehat{\beta}_1$ is distributed, in the limit, as a normal random vector (see Fuller, 1987, Theorem 2.3.2).

Related Methods

Regression with Instrumental Variables

In the preceding sections we have assumed implicitly that when the variance of the measurement error is not known, it can be estimated from data at hand. Sometimes, however, it is not possible to obtain an estimate of the measurement error variance. Instead, we assume that we have available another variable, which we denote Z, and which is known to be correlated with x. If Z is independent of e and u, and Z is correlated with x, we say that Z is an *instrumental variable* (*see* Instrumental Variables in Statistics and Econometrics). Fuller (1987) presents an in-depth discussion of instrumental variable estimation in linear models (Sect. 1.4 and 2.4).

He shows that method of moments estimators for the regression coefficient can be obtained by noticing that the first and second sample moments of the vector (Y, X, Z) are the set of minimal sufficient statistics for the model parameters. The resulting estimators are

$$\begin{aligned}\widehat{\beta}_1 &= s_{XY}^{-1}s_{YZ}\\ \widehat{\beta}_0 &= \overline{Y} - \widehat{\beta}_1\overline{X}\end{aligned} \qquad [20]$$

where s_{XZ} and s_{YZ} are the sample covariances of the covariate and the response variables with the instrumental variable, respectively. Because the sample moments are consistent estimators of the population moments, the estimators in (20) are consistent estimators of β_0 and β_1. Notice, however, that if the assumption $\sigma_{xZ} \neq 0$ is violated, the denominator in the expression for $\widehat{\beta}_1$ above estimates zero and the estimator is therefore not consistent.

Amemiya (1985, 1990a, 1990b), Carroll and Stefanski (1994) and Buzas and Stefanski (1996) discuss instrumental variable estimation in nonlinear models.

Factor Analysis

Factor analysis is heavily used in psychology, sociology, business, and economics (*see* Factor Analysis and Latent Variable Models in Personality Psychology). We consider a model similar to the model used for estimating an instrumental variable, with a few additional assumptions. The simplest version of a factor model is

$$\begin{aligned}Y_1 &= \beta_{01} + \beta_{11}x + e_1\\ Y_2 &= \beta_{02} + \beta_{12}x + e_2\\ X &= x + u\end{aligned} \qquad [21]$$

Here, (Y_1, Y_2, X) are observed. We assume that the coefficients associated to x are nonzero, and that $(x, e_1, e_2, u)' \sim N[(\mu_x, 0, 0, 0)', \mathrm{diag}\,(\sigma_x^2, \sigma_{e1}^2, \sigma_{e2}^2, \sigma_u^2)]$.

In factor analysis, the unobservable variable x is denoted *common factor* or *latent factor*. For example, x might represent intelligence, and the observed variables (Y_1, Y_2, X) might represent the individual's scores in three appropriate tests. The ratio of the variance of x to the variance of the response variable is called the *communality* of the response variable. For example, the communality of Y_1 above is calculated as

$$\lambda_1^2 = \frac{\beta_1^2\sigma_x^2}{\beta_1^2\sigma_x^2 + \sigma_{e1}^2} \qquad [22]$$

Note that λ_1^2 is equal to the reliability ratio that was presented in Section Simple Linear Regression and Measurement Error.

Estimators for β_{11} and for β_{12} can be obtained using the same methods that were used for estimating instrumental variables in Section Regression with Instrumental Variables. For example, $\widehat{\beta}_{11}$ is the instrumental variable estimator of β_{11} under the model $Y_1 = \beta_{01} + \beta_{11}x + e$ using Y_2 as an instrumental variable. Similarly, an estimator for β_{12} is obtained using Y_1 as an instrumental variable.

For an extensive discussion of factor analysis, refer to Jöreskog (1981) and Fuller (1987).

Regression Calibration

Suppose that for each sample item we observe Y, X, and $\mathbf{w}$, where $X = x + u$, and $\mathbf{w}$ is a vector of covariates measured without error. The idea behind regression calibration is simple. Using information from X and $\mathbf{w}$, estimate the regression of x on (X, $\mathbf{w}$). Then fit the regression model for Y using $E\{x|X, \mathbf{w}\}$ using standard methods. The standard errors of the parameters in the regression model for Y must be adjusted to account for the fact that x is estimated rather than observed.

Estimation of the regression of x on (X, $\mathbf{w}$) is straightforward when replicate observations are available. Suppose that there are m replicate measurements of x for each individual, and that $\overline{X}$ is their mean. In that case, the *best linear estimator* of x is $E\{x|\overline{X}, w\}$, where

$$E\{x|\overline{X}, w\} = \mu_x + \begin{pmatrix}\sigma_x^2\\ \Sigma_{wx}\end{pmatrix} \times \begin{bmatrix}\sigma_x^2 + \sigma_u^2/m & \Sigma_{xw}\\ \Sigma_{xw}' & \Sigma_{ww}\end{bmatrix}^{-1}\begin{pmatrix}\overline{X} - \mu_x\\ \mathbf{w} - \mu_w\end{pmatrix} \qquad [23]$$

Moment estimators for all unknown parameters in the expression above can be obtained as long as replicate

observations are available and an estimator for the unknown measurement error variance can be computed. If replicate observations are not available, it is possible to use an external estimate of the measurement error variance.

Regression calibration was proposed by Gleser (1990). Carroll (1995, Chap. 3) discusses regression calibration in nonlinear models.

An alternative approach called SIMEX (for simulation extrapolation) that is well suited for the additive measurement error case was proposed by Cook and Stefanski (1994).

Nonlinear Models and Measurement Error

Carroll (1995, Chap. 6) presents an in-depth discussion of the problem of estimating the parameters in a nonlinear model when one or more of the covariates in the model are measured with error. Most of their discussion assumes that the measurement error is additive and normal, but some results are presented for more general cases. Other references include Amemiya (1990), Gleser (1990), and Roeder et al. (1996).

Carroll (1995) presents two approaches for estimating the parameters in the nonlinear model subject to measurement error, denoted *conditional score* and *corrected score* methods, that are based on an *estimating equations* approach. In either case, the resulting estimators do not depend on the distribution of x.

The *conditional score* method is derived for the case of the canonical *generalized linear model* (McCullagh and Nelder, 1989) (*see* Linear Hypothesis). Without loss of generality we discuss the case where both x and w are scalar valued. The conditional density of Y given (x, w) is given by

$$f(y|x, w, \Theta) = \exp\left\{\frac{y\eta - D(\eta)}{\phi} + c(y, \phi)\right\} \qquad [24]$$

(expression 6.4 in Carroll, 1995), where $\eta = \beta_0 + \beta_1 x + \beta_2 w$ is called a *natural parameter*, $\Theta = (\beta_0, \beta_1, \beta_2, \varphi)$ is the unknown parameter to be estimated, and where the first and second moments of the distribution of Y are proportional to the first and second derivatives of $D(\eta)$ with respect to η. The form of η, $D(\eta)$ φ and $c(y, \varphi)$ depends on the model choice.

If x were observed, then Θ is estimated by solving the following equations

$$\sum_{i=1}^{n}\left\{Y_i - D^{(1)}(\eta_i)\right\}\begin{pmatrix}1\\ w_i\\ x_i\end{pmatrix} = 0$$

$$\sum_{i=1}^{n}\left[\left(\frac{n-1}{n}\right)\phi - \frac{\left(Y_i - D^{(i)}(\eta_i)\right)^2}{D^{(2)}(\eta_i)}\right] = 0 \qquad [25]$$

where $D^{(k)}$ (η) is the kth order partial derivative of D (η) with respect to η.

We now assume that x is measured with normal additive measurement error with variance σ_u^2. A sufficient statistic Δ can be found for x (Stefanski and Carroll, 1987) so that the distribution of Y conditional on (Δ, w) has the same form as the density given in (24). The form of the functions D (η), η, φ and c (y, φ) must be modified accordingly (see, for example, Carroll, 1995, p. 127). Therefore, this suggests that an estimator for Θ when x is observed with measurement error can be obtained by solving a set of equations similar to eqn [25].

The approach described above can be used only in the case of canonical generalized linear models. An approach applicable to the broader class of generalized linear regression models is the *corrected score* method, also derived under an estimating equations framework. Suppose, first, that x is observable, and that an estimator of Θ is obtained by solving

$$\sum_{i=1}^{n}\xi(Y_i, x_i, w_i, \Theta) = 0 \qquad [26]$$

where ξ is a likelihood score from the model when x is observed without measurement error. Suppose now that we can find a function $\xi * (Y, X, w_i, \Theta, \sigma_u^2)$, such that

$$E\{\xi * (Y, X, w_i, \Theta)|Y, x, w\} = \xi(Y, x, w, \Theta) \qquad [27]$$

for all (Y, x, w). An estimate for the unknown parameter Θ can then be obtained by solving eqn [26] where the corrected score $\xi*$ is used in place of ξ. Corrected score functions that satisfy eqn [27] do not always exist, and when they do exist they can be very difficult to find. Stefanski (1989) derived the corrected score functions for several models that are commonly used in practice.

A Brief Historical Overview

The problem of fitting a simple linear regression model in the presence of measurement error was first considered by Adcock (1877). Adcock proposed an estimator for the slope in the regression line that accounted for the measurement error in the covariate for the special case where $\sigma^2{}_a = \sigma^2{}_e$. The extension to the p-variate case was presented by Pearson (1901).

It was not until the mid-1930s that the terms *errors in variables models* and *measurement error models* were coined, and a systematic study of these types of model was undertaken. The pace of research in this area picked up in the late 1940s, with papers by Lindley (1947), Neyman and Scott (1951), and Kiefel and Wolfowitz (1956). These authors addressed issues of identifiability and consistency in measurement error models, and proposed various approaches for parameter estimation in those models. Lindley (1947) presented maximum likelihood estimators for the slope in a simple linear regression model with additive measurement error for the functional model. He concluded that, when the two variance components are unknown, the method of maximum likelihood cannot be used for estimating β_1, as the resulting estimator must satisfy the relation $\widehat{\beta}_1, \widehat{\sigma}_u^2 = \widehat{\sigma}_e^2$. Solari (1969) later showed that this unexpected result could be explained by noticing that the maximum likelihood solution was a saddle-point and not a maximum of the likelihood function. Lindley (1947) also showed that the generalized least squares estimator of the slope is the maximum likelihood estimator when the ratio of variances is assumed known.

Extensions of the simple linear regression model to the multiple regression model case, with one or more covariates measured with error were presented in the late 1950s, 1960s and 1970s. Excellent early in-depth reviews of the literature in measurement error models are given by Madansky (1959), and Morton (1981).

In the early 1990s, Schmidt and Rosner (1993) proposed Bayesian approaches for estimating the parameters in the regression model in the presence of measurement error. More recently, Robins and Rodnitzky (1995) proposed a semi-parametric method that is more robust than the maximum likelihood estimator of the slope in structural models when the distributional assumptions are not correct. Carroll et al. (1997), however, showed that the Robins and Rodnitzky estimator can be very inefficient relative to the parametric estimation when the distributional assumptions are correct. Roeder et al. (1996) and Carroll et al. (1999) have argued that the sensitivity of the maximum likelihood estimator to model specification can be greatly reduced by using flexible parametric models for the measurement error. In particular, the authors suggest that a normal mixture model be used as the flexible model. In the 1999 paper, Carroll et al. (1999) proceed from a Bayesian viewpoint, and use Markov chain Monte Carlo methods to obtain approximations to the marginal posterior distributions of interest.

The literature on measurement error models is vast, and we have cited a very small proportion of the published books or manuscripts. In addition to the review articles listed above, the text books by Fuller (1987) and Carroll (1995) are widely considered to be the best references for linear and nonlinear measurement error models, respectively. The recent manuscript by Stefanski (2000) cites several papers that have appeared in the literature since 1995.

Abstract

The principles of representational measurement theory are expounded in historical and contemporary perspective, including a preliminary formulation of representation, uniqueness, and meaningfulness. The whole article is based on the concept of an ordered relational structure. The definition and representation theorems of extensive and difference structures are presented and discussed. These are ordered relational structures with operations or difference like relations defined on them. Stevens's classification of scale type (i.e., the classical ratio, interval, and ordinal scales) and its modern development in the context of the automorphism group of a measurement structure are dealt with, leading naturally to the problem of meaningfulness of numerical statements. Finally problems and applications of the representational theory of measurement are pointed out.

The representational theory of measurement – RTM for short – is a sort of 'interface' between a qualitative, empirical, or material domain of research and the use of numbers to quantify the empirical observations and to draw inferences from the data. Roughly, the main tenets of RTM consist of the following steps (for definition of the main concepts *see* Ordered Relational Structures):

1. Describe the situation under scrutiny by a qualitative relational structure, consisting of a base set A and a finite number of relations. Among these relations is usually an order relation and sometimes special elements such as units. These entities are the primitives of the structure. They must have an empirical identification. The properties of this qualitative relational structure are stated as conditions or axioms on its primitives, which are true statements about the structure, at least in the intended empirical identification.
2. Verify by empirical procedures (experiments, observations) the truth of those conditions that are testable (which should be almost all of them) and find arguments (plausibility, consequences of failure) for those that are not testable.
3. Find a structure with a numerical base set (a subset of $\mathbb{R}$ or $\mathbb{R}^n$) and find homomorphism between both structures. Finding a homomorphism may consist of providing a representation theorem, which essentially, states the existence of at least one homomorphism.
4. Find all homomorphisms between the qualitative and the numerical structure. This step amounts to proving a uniqueness theorem, which in most cases yields a procedure to calculate any homomorphism from a given one.
5. Clarify on the basis of the uniqueness properties of the set of homomorphisms which numerical statements about the empirical domain are meaningful and which are not. Meaningful statements can be used for further analysis, such as statistical tests.

This theory is thoroughly described in the three volumes *Foundations of Measurement* (see Krantz et al., 1971; Suppes et al., 1989; Luce et al., 1990). Other comprehensive expositions, differing slightly in emphasis and philosophical argumentation, are Pfanzagl (1971), Roberts (1979), and Narens (1985).

History and Contemporary a Formulation of Measurement Within RTM

The above kind of formalization of measurement goes back to Helmholtz (1887). Hölder (1901) was the first to prove a representation theorem in the above sense. One version or other of Hölder's theorem lies at the heart of almost all representation theorems proved in the following years up to the present time. It did not, however, stimulate much research until the late 1950s. The 1930s and 1940s saw an ongoing debate about the measurability of sensory variables, which seemed to some a prerequisite to laying a firm foundation for psychology, not unlike that of most of the natural sciences. In this debate, the introduction of scale types by Stevens (1946) was a cornerstone. The search for a precise formulation led to the model-theoretic formulation of Scott and Suppes (1958). This framework was extended in the three volumes *Foundations of Measurement* (Krantz et al., 1971; Suppes et al., 1989; Luce et al., 1990) and in the other books cited above.

In its present form, RTM consists of two relational structures $\mathscr{A}$ and $\mathscr{N}$. The base set of $\mathscr{N}$ is some subset of the reals or a real vector space. The objects which are empirically identified with the elements of A, the base set of $\mathscr{A}$, can be measured if it is possible to give or construct a homomorphism φ between the two structures. In most cases the structure $\mathscr{A}$ contains among its relations a weak order $\lesssim$. Some authors distinguish functions and constants such as a unit element from the proper relations. In our notation, these variants are all subsumed in $(R_i,\ i \in I)$. This sequence of relations can even be infinite. Sometimes it is necessary to endow the structures with several base sets and relations among them. This case can also be formulated within the present scheme, although it looks a bit clumsy.

The following are three of the major issues that confront RTM:

Representation: Does there exist a homomorphism between two structures, the qualitative and the numerical one, i.e., is there a mapping which preserves structure? This question is concerned with the measurability in principle of the variables under scrutiny.

Uniqueness: How can one describe the set of all representations of a given structure? This topic includes questions about the precise definition of scale type.

Meaningfulness: Which assertions about a measurement structure make sense, which do not? What is the meaning of numerical operations performed on the scale values? These questions are relevant to the applicability of statistical tests and to the content of descriptive indices.

The representation question is answered in RTM by formulating representation theorems; the next section gives two prominent examples. The uniqueness problem was initially dealt with by describing the set of all homomorphisms, this kind of result is usually part of the respective representation theorems (see Section 'Representation Theorems'). However, the modern theory differs in several aspects from this approach (see Section 'Scale Type and Modern Theory: Automorphisms of Measurement Structures'). The discussion of meaningfulness seems to have gone way beyond RTM. Several notions of invariance and meaningfulness have been proposed and analyzed, partly under the headline of dimensional analysis. We give but a short overview in Section Meaningfulness.

Representation Theorems

The procedure outlined in the introductory paragraph and the formal definition is exemplified in this section by presenting a few representation and uniqueness theorems and by discussing examples. Basically, there are a few general properties that can be exploited to produce relational structures which can be successfully mapped into a numerical structure. Primarily these are ordered structures. The empirical identification of the elements of the base set and the order relation is in most cases rather straightforward. The other relations of the structures are operations, or are derived from the comparison of intervals, and the property of conjointness (*see* Measurement Theory: Conjoint). In the present article we focus on extensive structures and difference structures.

Extensive Measurement

Our first structure was also historically the first to be considered. It goes back to Helmholtz (1887). It postulates a qualitative ordering and a concatenation operation, i.e., a binary operation $\circ$: $A \times A \to A$ which resembles the operation of addition of real numbers.

Definition 1. Let A be a nonempty set, $\lesssim$ a binary relation on A, and $\circ$ a closed operation on A, i.e., for all elements a, $b \in A$ there exists an element $c \in A$ such that $a \circ b = c$. The triple $(A, \lesssim, \circ)$ is a closed extensive structure if the following conditions (E1), (E2), (E3), and (E4) are satisfied for all a, b, c, $d \in A$; if in addition (E5) is satisfied it is a positive structure.

(E1) $\lesssim$ is a weak order on A, i.e., it satisfies $a \lesssim b$ and $b \lesssim c$ implies $a \lesssim c$, and $a \lesssim b$ or $b \lesssim a$.
(E2) $a \circ (b \circ c) \sim (a \circ b) \circ c$.
(E3) $a \lesssim b$ iff $a \circ c \lesssim b \circ c$ iff $c \circ a \lesssim c \circ b$.
(E4) If $a \prec b$, then for any c, d there exists a positive integer n such that $na \circ c \lesssim nb \circ d$, where na is defined inductively by $1a = a$ and $(n + 1)a = na \circ a$.
(E5) $a \prec a \circ b$.

The example of weights in Section 'Representation Theorems' of the article *Ordered Relational Structures* can be regarded as such a structure if one is willing to accept certain idealizations. It formalizes the measurement of mass by comparing objects on a pan balance. Another obvious example is the measurement of length, also modulo several idealizations.

The following theorem not only guarantees the existence of a numerical representation (a homomorphism into the reals) but also states that this existence implies the conditions of Definition 1. It reads as follows:

Theorem 1. Let $(A, \lesssim, \circ)$ be a system with $\lesssim$ a binary relation and $\circ$ a binary operation on A. Then $(A, \lesssim, o)$ is a closed extensive structure if and only if there exists a function φ: $A \to \mathbb{R}$ such that for all a, $b \in A$

1. $a \lesssim b$ iff $\varphi(a) \leq \varphi(b)$;
2. $\varphi(a \circ b) = \varphi(a) + \varphi(b)$.

Another function φ': $A \to \mathbb{R}$ satisfies these two properties iff there is a constant $r \in \mathbb{R}$ such that $\varphi' = r\varphi$. The structure is positive iff $\varphi(a) > 0$.

The first part is the existence theorem, the second part the uniqueness theorem. The latter can be rephrased as: A closed concatenation structure allows the measurement of the objects on a ratio scale.

This result has been extended in several ways. One point of improvement consists of dropping the assumption of closedness of the operation. A closed operation forces the possibility to concatenate arbitrary large and arbitrary small elements, an assumption that might be too strong in practice. Krantz et al. (1971) give sufficient conditions when the operation is not necessarily closed. Other modifications are concerned with minimal and maximal elements in the structure, such as the velocity of light in relativistic velocity concatenation. Recently, this problem has been generalized by regarding 'singular points' in the structure, i.e., elements that behave differently with respect to $\circ$ than do the rest of the elements.

Difference Measurement

While extensive operations abound in physics, they are rarely encountered in social sciences. However, the comparison of intervals is often used in psychological experiments. For instance, one can ask subjects whether the political system of two nations a, b is more similar to each other than that of the nations c, d. In economics the probability of choosing one alternative over another is used as an index of the size of a utility interval. In psychophysics, the method of bisection requires an observer to choose a stimulus whose value on some psychological scale such as loudness or brightness is between two given stimuli, such that the ensuing sensory differences are equal. This procedure assumes that people are able to compare intervals. Further examples are described in Chapter 4 of Krantz et al. (1971).

The following definition assumes a weak order $\lesssim$ on a subset A^* of pairs. For simplicity, the reader might assume that exactly one of the pairs ab and ba is in A^* for all a, $b \in A$.

The definition and theorem are more general, but this is the most important case.

Definition 2. Let A be a nonempty set, A^* a nonempty subset of the Cartesian product $A \times A$, and $\lesssim$ a binary relation on A^*. The triple $(A, A^*, \lesssim)$ is a positive difference structure if for all $a, b, c, d, a', b', c', a_1, a_2, \ldots \in A$.

(D1) $\lesssim$ is a weak order on A^*.
(D2) if $ab, bc \in A^*$, then $ac \in A^*$.
(D3) If $ab, bc \in A^*$, then $ab, bc \prec ac$.
(D4) If $ab, bc, a'b', b'c' \in A^*$, $ab \lesssim a'b'$, and $bc \lesssim b'c'$, then $ac \lesssim a'c'$.
(D5) If $ab, cd \in A^*$ and $ab \succ cd$ then there exist $d', d'' \in A$ such that $ad', d'b, ad'', d''b \in A^*$ and $ad' \sim cd \sim d''b$.
(D6) If $a_1, a_2, \ldots$ is a strictly bounded standard sequence, i.e., $a_i\, a_{i+1} \in A^*$ and $a_i a_{i+1} \sim a_1 a_2$ for $i = 1, 2,$. and for some $d'd'' \in A^*$ holds $a_1 a_i \prec d'd''$, then it is finite.

Theorem 2. Let $(A, A^*, \lesssim)$ be a positive difference structure. Then there exists a function $\psi: A^* \to \mathbb{R}^+$ such that for all $a, b, c, d \in A$

1. if $ab, cd \in A^*$, then $ab \lesssim cd$ iff $\psi(ab) \leq \psi(cd)$;
2. if $ab, bc \in A^*$, then $\psi(ac) = \psi(ab) + \psi(bc)$

If ψ' is another function with these properties, then there is some $r > 0$ such that $\psi' = r \cdot \psi$.

If for all $a \neq b$, $a, b \in A$ either ab or ba in A, then there exists $\varphi: A \to \mathbb{R}$ such that for all $ab \in A^*$, $\psi(ab) = \varphi(b) - \varphi(a)$. If φ' has the same property, then for some $s \in \mathbb{R}$, $\varphi' = \varphi + s$.

The uniqueness assertion of this theorem roughly says that the intervals, i.e., the elements of A^*, are measured on a ratio scale, while the elements of A are measured on an interval scale.

Other difference structures, called algebraic-difference structures, have been developed, allowing both for positive and negative intervals (Krantz et al., 1971). Even the case of two simultaneous orderings of intervals compatible in a well-defined sense has been considered. The representation theorems guarantee the measurement of one ordering by differences of the representing function, while the other is represented by their ratios. A modification of this theorem was used by Suck (1998) for a measurement theoretic characterization of the exponential distribution.

Comments on the Axioms

Some remarks are in order regarding the nature of the different axioms. Some describe particular properties of the structures, such as the order axioms, or associativity (E2) in Definition 1, or (D4) in Definition 2. They are called *structural* and are all testable for given elements of A. Another class of axioms are the solvability conditions such as (D5). They postulate the existence of certain elements, given a few others, such that a given 'equation' is solved. Often a consequence of this kind of axiom is that the structure becomes infinite. Characteristically, a solvability axiom is often a part of conditions that are sufficient for numerical representations; however, it is not a necessary condition. Testing it is a delicate matter if one does not find elements d', d'' in (D5), then their nonexistence is in general not proved.

A third class of conditions are Archimedean axioms, with Definition 1 (E4) and Definition 2 (D6) being examples. They are necessary for a representation with real numbers, because $\mathbb{R}$ satisfies a similar property (for all $x > y > 0$ there is an integer n such that $ny > x$). In ordered relational structures, the corresponding formulation employs the notion of standard sequences. These are increasing or decreasing sequences of elements of A, which are equally spaced in some sense specific for the structure. Examples are the sequences in (E4) and (D6).

Standard sequences are also very important for the construction of the homomorphisms in the representation theorems. This fact becomes clear if one studies the proofs of results such as Theorems 1 and 2. The key idea is as follows: a first standard sequence $a_1, a_2, \ldots$ is chosen. An element $a \in A$ is enclosed in $a_k \lesssim a \prec a_{k+1}$. The value k is taken as a first approximation to $\varphi(a)$. Then a second standard sequence $b_1, b_2, \ldots$ is constructed with each $b_{2i} = a_i$, i.e., a new element is introduced between two consecutive elements of the first sequence. If now $b_i \lesssim a \prec b_{i+1}$ then $i/2$ is the second approximation to the desired $\varphi(a)$. Proceeding in this way, a sequence of approximations is constructed. If this sequence can be shown to converge, then one has a value $\varphi(a)$. This φ can in many cases be shown to be one homomorphism. Other homomorphisms drop out by beginning with a different standard sequence. The uniqueness statements are derived from observing how these sequences are interrelated. This kind of proof mimics in some sense the actual procedures used in physics to measure objects. It is constructive and, depending on how many approximating steps are employed, controls the accuracy of the measurement.

Scale Type

Stevens (1946) introduced the concept of 'scale type' in response to a vivid debate on the possibility of evaluating subjective sensory events quantitatively. Much of the development of the present form of RTM in the 1950 and 1960s was influenced by the endeavor to give a sound foundation to Stevens' classical scale types, namely nominal, ordinal, interval, and ratio scales.

Roughly, the idea is to characterize scale type by describing the set of all homomorphisms of a representation in a uniqueness theorem. Such a description can be performed by giving the set of admissible transformations of a given homomorphism. Thus, if any strictly increasing transformation of a representation is admissible, then we have an ordinal scale if transformations of the form $x \to rx + s$ with $r > 0$ are admissible, we have an interval scale, and with $x \to rx$ we have a ratio scale. If necessary, one can define a nominal scale as one with all injective mappings (*see* Ordered Relational Structures) as admissible transformations.

Over time this simple theory needed several modifications. Log-interval scales and difference scales were introduced, mainly because the choice of the numerical structure was recognized to be highly arbitrary. Furthermore, not all scales could be given a clear place in this scheme. Roberts and Franke (1976) found that the scale type of semiorders (*see* Partial Orders) was 'irregular' compared with the previously considered types. This discussion was soon linked with invariance considerations and the meaningfulness problem. The scale type question was finally resolved by the work of Louis Narens (e.g., Narens, 1981a,b), which led to the consideration of the automorphism group and the degree of homogeneity and

uniqueness of an ordered structure (*see* Ordered Relational Structures). The next section discusses this theory.

Modern Theory: Automorphisms of Measurement Structures

The article on *Ordered Relational Structures* presents the homogeneity-uniqueness definition of scale type. Using automorphisms instead of homomorphisms and isomorphisms in this context frees the scale type and meaningfulness discussion from the arbitrariness of the choice of the representing structure. Furthermore, instead of applying an admissible transformation to a given homomorphism, one can apply an automorphism to the structure and then use the homomorphism. This way the possible representations drop out more naturally.

The first major success of this approach, which has been championed primarily by Narens, was the successful characterization of scale types (M, N) on the reals in the Alper/Narens Theorem. The type $(1, 1)$ corresponds to a ratio scale, $(2, 2)$ is an interval scale, $(1, 2)$ is something in between, and (∞, ∞) is an ordinal scale. Other scale types do not exist if the homomorphism is onto a real interval. This deep result explains why science does not employ scales of a type intermediate between the interval and ordinal type. However, if the range of the homomorphism is the rational numbers, Cameron (1989) and Macpherson (1996) showed that all types (M, N) with $1 \leq M \leq N$ are possible.

The main problem is now to classify structures by scale type. In the investigation of this question a subset of the automorphism group, namely the translations, plays a crucial role. An automorphism $\tau \in \mathrm{Aut}_{\mathscr{A}}$ is a *translation* if $\tau(a) \neq a$ for all $a \in A$ or if it is the identity map id_A. Luce and Narens (1994) formulate three major questions about translations which arose from the analysis of the proof of the Alper/Narens theorem:

1. Do the translations form a group?
2. Can the translations be ordered such that they satisfy an Archimedean property?
3. Are the translations 1-homogeneous?

If all these questions are answered affirmatively, a numerical representation can be constructed (see Luce and Narens, 1994).

Thus, a major problem is to find structural conditions that imply these three properties of the translations. But this seems to be a difficult problem, and not very much is known about it (see Luce, 2001). However, this shift of focus in the scale type discussion has already proved fruitful and has considerably increased the understanding of the philosophical problems of measurement. Possibly, final answers require a simultaneous solution of the meaningfulness problem which we discuss next.

Meaningfulness

In this section a short overview of the various aspects of the meaningfulness problem is given.

The 'meaning' of words or statements used to be a much debated issue in analytical philosophy in the first half of the twentieth century, as witnessed, for example, in the work of Carnap and others. In the same vein, and probably influenced by the philosophical discussion, the meaningfulness problem has been of interest from the very beginning of RTM. It is just the meaning of statements involving numerical values which is being debated. To give an example, consider the two statements:

1. The ratio between yesterday's maximum temperature and today's is 2.
2. The ratio between the difference of yesterday's maximum and minimum temperature and today's difference of the same values is 2.

Clearly, Statement (1) depends on the employed temperature scale. If it is correct using a Fahrenheit scale it is wrong in a Celsius scale, and vice versa (except for a few particular values). The second statement remains true or false in each temperature scale which is used nowadays. As a result, (1) seems meaningless, while (2) has a chance to be meaningful.

In its first formulation, the meaningfulness problem was closely linked to the uniqueness of scales and to scale type. Roughly, one seemed to settle with the formulation: a statement involving numerical scale values is meaningful if its truth value (i.e., true or false) does not change when an admissible transformation is applied to any of the scale values occurring in its formulation.

This approach falls short for several reasons, among which is the detection of irregular scales by Roberts and Franke (1976). More advanced theories of meaningfulness distinguish several concepts of invariance, such as reference and structure invariance. By the former it is understood that a relation is invariant under permissible transformations, while by the latter it is invariant under endomorphisms, i.e., homomorphisms of the structure into itself. These invariance properties were shown to provide necessary conditions on numerical relations for empirical meaningfulness. By contrast, the definition of a relation using the primitives of the structure may influence its meaningfulness. This is an intricate question connecting the meaningfulness problem to questions of definability.

Another aspect is dimensional analysis, which is a powerful tool in physics. The idea of this theory is to consider an equation involving the values of several different measurement homomorphisms, such as $f(x_1, \ldots, x_k) = 0$. If admissible transformations are applied to the scale values, the postulation of in-variance narrows down the possibilities for f. in most cases, this argument leads to a functional equation which, when solved, gives the form of the physical law underlying the original equation. Luce (1959) applied this principle to psychophysical laws. Roberts and Rosenbaum (1986) undertook a systematic investigation of this technique, and Narens and Mausfeld (1992) presented a theory on the relationship of the psychological and the physical in psychophysics resulting in what they call an 'equivalence principal'. This method turns out to be a tool to sort out quantitative formulae and statements that have psychological significance. The role of dimensional analysis to find or discuss 'lawful' expressions is elaborated at a more advanced level in Luce (1978) and Chapter 22.7 of Luce et al. (1990).

One of the issues of the meaningfulness discussion was the question of meaningful statistics. In it an answer is sought to the question of which statistical procedures are applicable to which kind of data. For example, one can look at the test statistic of a *t*-test. It consists of a ratio of a difference of mean values and a standard deviation (or a 'mixed' standard deviation calculated from two samples). It is easy to see that this value is invariant under affine transformations of the data, but may vary considerably if the data are transformed monotonically. Does this fact imply that the *t*-test is applicable to interval scales and not to ordinal scales? Opinions on this question seem to differ widely. Luce et al. (1990) give an overview of what RTM can contribute to this question. Their point is that it is in general not the employed statistical value (e.g., the mean value) itself which might be inappropriate, but rather the numerical relations involving this value. Therefore, a difference has to be made between the meaningfulness of hypotheses on populations and the meaningfulness of statistics used for the description of samples.

A completely new way of looking at the meaningfulness issue was recently suggested by Narens (2002). He seems to turn the tables, in the sense that RTM is justified in terms of a new formulation of meaningfulness. In this formulation one still captures the domain of interest in a qualitative relational structure, but instead of deriving meaningfulness from invariance properties of this structure, one assumes a theory of meaningfulness in terms of which the concept of a meaningful scale can be formulated. In his paper it is shown that for each (in this sense) meaningful scale there exists a mathematical representing structure such that the scale consists of homomorphisms between these structures. Thus, the meaningful problem is solved by giving it a more fundamental place in the scientific process. Future discussion and elaboration of this point of view will decide on its viability.

Problems of RTM

Philosophical debate regarding the foundations of RTM continues – see, for instance, critiques by Michell (1986), Niederée (1987, 1992, 1994), and Dzhafarov (1995). The main points of criticism are analyzed and discussed in Luce and Narens (1994).

A major driving force of RTM has been the idea that applied scientists would test the axioms of representation theorems, and if the fit was satisfactory, they would construct a scale accordingly, using the uniqueness part for a justification of the operations performed in the course of the research on the topic. This program, if it was a program, seems not yet to have been implemented. Others would say it has failed. There are very few attempts to test axioms for this purpose. Luce's (2000) book on utility theory is an exception and may point a way of renewing this program.

A major obstacle to an application of RTM in the way described is the lack of a satisfactory error theory of measurement within RTM. To what extent must an axiom be violated to be sure it does not hold? To give an example: even for physical length measurement, one can observe many instances of violations of the testable axioms of Theorem 1 (see Section 'Extensive Measurement'). This will necessarily happen if the investigated objects differ only very little in length, less than the accuracy of the measuring device.

There have been numerous attempts to extend the classical 'deterministic' RTM to 'nondeterministic' versions by adding a probabilistic structure. However, none has provided a practical device for a theory of measurement error within RTM.

Another critical issue is the almost ubiquitous use of infinite structures. More than that the most elegant and useful results, such as the Alper/Narens Theorem, are obtained for continuum structures, i.e., ordered structures which satisfy Dedekind completeness (all infima and suprema exist, *see* Ordered Relational Structures). It can be surmised that a powerful error theory calls for mappings on a continuum.

The idea of embedding structures in Dedekind complete ones using extension procedures such as Dedekind cuts works in some cases but is intricate in others (*see* Ordered Relational Structures and Partial Orders). In what sense finite data sets are approximating such structures is a problem of theoretical importance for which not very much is known as yet. Sommer and Suppes (1997) proposes a critical approach to the use of the continuum in this context.

There are more results needed on classification by scale type. In particular, structural equivalents of homogeneity and uniqueness of automorphisms are not yet known. By structural equivalents, we mean conditions formulated within the structure and not within the automorphism group. Likewise, it is unclear how properties of the translations can be formulated or derived within $\mathscr{A}$.

Finally, the meaningfulness question is one of the outstanding open problems of RTM. The recent approach of Narens (submitted) mentioned in Section 'Meaningfulness' appears completely new from the perspective of RTM, and it might possess the quality of a Copernicanean revolution.

Applications of RTM

It has already been mentioned that axiom testing is only rarely performed. But there are such investigations, mostly in connection with conjoint measurement (*see* Measurement Theory: Conjoint Analysis Applications). Much of the research on color vision, spatial vision, and other psychophysical questions uses representations of measurement structures. The benefit of RTM in such investigations is often theoretical: it provides a firm basis for formulating hypotheses and performing tests. As an example we cite Heller (1997) on binocular space perception and the elaborate mathematical development ensuing from this paper (see Aczél et al., 1999).

An interesting application of RTM can be found in dimensional analysis and the derivation of numerical laws in physics and psychophysics. Chapter 10 of Krantz et al. (1971) is the paradigm for this kind of application. Since then many results have been published. We cite one important article: Narens and Mausfeld (1992).

Finally, we mention the application of measurement theory in decision making. Expected utility theory, its subjective counterparts, e.g., Prospect theory, rank dependent utility (Luce, 2000), etc all rely to a great extent on results from RTM. This tendency is kept to the present day and is

likely to remain so for some time. Luce (2000) is an outstanding recent example. The papers Luce and Narens (1994) and Luce (1995) give an in-depth overview of the general discussion.

Abstract

The theory of conjoint measurement concerns quantitative measurement of a qualitative aspect of objects that are characterized by a number of attributes. The qualitative aspect is often a subjective notion of value or preference, and its quantitative counterpart is a sum of numerical values or utilities over the attributes. If object x is characterized by levels x_1, x_2, and x_3 of three attributes, its numerical valuation is $u_1(x_1) + u_2(x_2) + u_3(x_3)$, where ui is a utility function for attribute i. A particular model of conjoint measurement for this case is based on axioms or assumptions about preferences between objects which imply the existence of u_1, u_2, and u_3 such that, for any two objects x and y, x is preferred to y if and only if $u_1(x_1) + u_2(x_2) + u_3(x_3) > u_1(y_1) + u_2(y_2) + u_3(y_3)$. The axioms make assumptions about ordering properties for preferences and tradeoffs among attributes that lead to the additive utility representation. A variety of axiomatic schemes arise from different attribute structures and different problem settings.

The theory of conjoint measurement is a branch of measurement theory in which objects described by several attributes are assigned numerical values that preserve an ordering of the objects by a qualitative relation such as preference or likelihood. Numerical values of objects usually are presumed to equal the sum of values assigned separately to each attribute. A conjoint measurement theory consists of the structure assumed for objects and their attributes, assumptions about the qualitative relation among objects, a numerical representation that connects the qualitative ordering of objects to numerical values, and a description of all sets of numerical values that satisfy the representation.

Objects and Attributes

The objects are members $x, y, \ldots$ of a subset X of the Cartesian product $X_1 \times X_2 \times \ldots \times X_n$ of $n \geq 2$ other sets referred to as attributes, factors, or criteria. When x_i is the member of attribute X_i associated with object x, $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n)$, … Any set of entities that share a common set of attributes could serve as X, including consumption bundles (each attribute is a good, x_i is the amount of attribute i in bundle x), investment portfolios (stocks, bonds), houses (location, style, size, cost), candidates for a position (education, experience, skills, quality of references), and a host of other possibilities.

A particular theory specifies the structure of the X_i and X. Structural aspects are the number of attributes, whether X equals or is a proper subset of $X_1 \times \ldots \times X_n$, and the nature of each X_i (finite, infinite but discrete, a continuum). One theory assumes that n is any integer greater than 1, X is an arbitrary subset of $X_1 \times \ldots \times X_n$, and every X_i is a finite set. Another assumes that $n = 2$, $X = X_1 \times X_2$, and each X_i, is a continuum. Additional restrictions on structure may be imposed by preference axioms.

Preferences and Axioms

Qualitative comparisons between objects in X are described by a binary relation $\succsim$ on X and induced relations $\succ$ and $\sim$ defined by $x \succ y$ if $x \succsim y$ and not $(y \succsim x)$, and $x \sim y$ if $x \succsim y$ and $y \succsim x$. When preference is primitive, $x \succsim y$ signifies that x is at least as preferable as y, $x \succ y$ means that x is strictly preferred to y, and $x \sim y$ denotes equally preferred objects. When objects are uncertain events, $x \succ y$ if x is judged to be at least as likely to occur as y, $x \succ y$ if x is judged to be more probable than y, and $x \sim y$ if x and y are considered equally likely.

Conditions imposed on the behavior of $\succsim$ on X are referred to as axioms. Although some axioms describe intuitively rational or reasonable behaviors, they are empirically refutable assumptions.

Ordering Axioms

It is often assumed that $\succsim$ is a weak order, that is, that $\succsim$ is complete (for all $x, y \in X : x \succsim y$ or $y \succsim x$) and transitive (for all $x, y, z \in X :$ if $x \succsim y$ and $y \succsim z$ then $x \succsim z$). When $\succsim$ is a weak order, $\sim$ is an equivalence relation (reflexive: $x \sim x$; symmetric: $x \sim y \Rightarrow y \sim x$; transitive) that partitions X into equivalence classes, with $x \sim y$ if and only if x and y are in the same class. A less common but more realistic axiom presumes only that $\succ$ is asymmetric $(x \succ y \Rightarrow \text{not}(y \succ x))$ and transitive, in which case $\sim$ is not necessarily transitive, as when $x \sim y$, $y \sim z$, and $x \succ z$. Still less common is the axiom which assumes that $\succsim$ is complete but not necessarily transitive.

Independence and Cancellation Conditions

Independence and cancellation conditions are needed for the additive utility representation in the next section. The most basic independence condition assumes that, for each i, if $x_i = z_i$ and $y_i = w_i$, and $x_j = y_j$ and $z_j = w_j$ for all $j \neq i$, then $x \succsim y \Leftrightarrow z \succsim w$. When $\succsim$ is a weak order on $X = X_1 \times \ldots \times X_n$, this implies that the relation $\succsim_i$ on X_i defined by

$$x_i \succsim_i y_i \text{ if } x \succsim y \text{ whenever } x_j = y_j \text{ for all } j \neq i \qquad [1]$$

is a weak order. Moreover, if $x_i \succsim_i y_i$ for all i, then transitivity implies $x \succsim y$, with $x \succ y$ if $x_i \succ_i y_i$ for at least one i.

A more general first-order cancellation axiom asserts that if $\{x_i, z_i\} = \{y_i, w_i\}$ for all i, then $x \succsim y \Leftrightarrow w \succsim z$. This extends to the general cancellation condition which says that if $m \geq 2$, if

$x^1, \ldots, x^m$, $y^1, \ldots, y^m \in X$, and if $y_i^1, \ldots, y_i^m$ is a permutation of $x_i^1, \ldots, x_i^m$ for every i, then it is not true that $x^j \succsim y^j$ for $j = 1, \ldots, m$ with $x^j \succ y^j$ for some j. The second-order cancellation axiom is the special case of general cancellation for $m = 3$. An instance for $n = 2$ is : it is false that $(x_1, x_2) \succsim (y_1, z_2), (y_1, y_2) \succsim (z_1, x_2)$, and $(z_1, z_2) \succ (x_1, y_2)$. Its $\sim$ version, whose conclusion is $\{x^1 \sim y^1, x^2 \sim y^2\} \Rightarrow x^3 \sim y^3$, illustrates a notion of higher-order tradeoffs and is sometimes referred to as the Thomsen condition.

Solvability and Archimean Axioms

Solvability axioms posit the existence of attribute values that allow compensating tradeoffs and thereby impose further restrictions on the X_i and X. An example for $n = 2$ is: for every $(x_1, x_2) \in X$ and every $y_1 \in X_1$, there is a $y_2 \in X_2$ for which $(y_1, y_2) \sim (x_1, x_2)$.

Archimedean axioms, sometimes referred to as continuity conditions, are technical conditions for infinite structures that ensure the existence of real-valued utilities in representations of $\succsim$. When each X_i is a nondegenerate real interval and $\succ$ is the lexicographic order defined by $(x_1, x_2) \succ (y_1, y_2)$ if $x_1 > y_1$ or $(x_1 = y_1, x_2 > y_2)$, there is no real-valued function u on X that satisfies $x \succ y \Leftrightarrow u(x_1, x_2) > u(y_1, y_2)$. Archimedean axioms forbid this type of noncompensatory dominance structure.

Additive Representations

The basic additive conjoint representation of $\succsim$ on X consists of a real-valued function u_i on X_i for $i = 1, \ldots, n$ such that, for all $y \in X$

$$x \succsim y \Leftrightarrow \sum_{i=1}^{n} u_i(x_i) \geq \sum_{i=1}^{n} u_i(y_i) \qquad [2]$$

An alternative is the multiplicative representation $x \succsim y \Leftrightarrow f_1(x_1) \ldots f_n(x_n) \geq f_1(y_1) \ldots f_n(y_n)$, where $f_i = e^{u_i}$. Other algebraic combinations of attribute utilities are discussed in Krantz et al. (1971) under polynomial measurement. Additional restrictions may be imposed on the u_i of eqn [2] for representations of qualitative probability.

Uniqueness

Let $v_i = au_i + b_i$ with $a > 0$ and $b_1, \ldots, b_n$ any real numbers. When eqn [2] holds, it holds also for $v_1, \ldots, v_n$ in place of $u_1, \ldots, u_n$. When no other transformations of the u_i satisfy eqn [2], the attribute utilities for the additive representation are unique up to similar positive affine transformations. The common $a > 0$ for the transformations preserves scale commensurability of the attribute utility functions. When X is finite, more general transformations are possible unless enough $\sim$ comparisons hold to force uniqueness up to similar positive affine transformations (Fishburn and Roberts, 1989).

Specific Theories

When X is finite, eqn [2] reduces to a finite number of linear inequalities with coefficients in $\{1, 0, -1\}$ which have a solution if and only if $\succsim$ satisfies weak order and general cancellation (Kraft et al., 1959; Fishburn, 1970; Krantz et al., 1971).

When the X_i are infinite, $X = X_1 \times \ldots \times X_n$, and $n \geq 3$ weak order, first-order cancellation, and an Archimedean axiom lead to u_i for eqn [2] that are unique up to similar positive affine transformations. A topological approach (Debreu, 1960; Fishburn, 1970; Wakker, 1989) also endows X with special topological structure, and an algebraic approach (Fishburn, 1970; Krantz et al., 1971) uses a solvability condition. Similar approaches apply for $n = 2$, where a second-order cancellation condition is also required.

Another weak-order theory considers a denumerable number of attributes that refer to successive time periods and involve notions of discounting and impatience (Fishburn, 1970). The relaxation of weak order where $\succ$ is asymmetric and transitive leads to the one-way representation

$$x \succ y \Rightarrow \sum_{i=1}^{n} u_i(x_i) > \sum_{i=1}^{n} u_i(y_i) \qquad [3]$$

for partially ordered preferences (Fishburn, 1970). Transitivity can be omitted without affecting additively as shown by the nontransitive additive conjoint representation

$$x \succsim y \Leftrightarrow \sum_{i=1}^{n} \phi_i(x_i, y_i) \geq 0 \qquad [4]$$

in which ϕ_i is a skew-symmetric $(\phi_i(a, b) + \phi_i(b, a) = 0)$ real-valued function on $X_i \times X_i$ (Fishburn, 1991).

Conjoint Measurement and Social Choice

Ideas from conjoint measurement have been applied to social choice theory (Fishburn, 1973) under the following interpretations. Each i indexes one of n voters, and $\succsim_i$ denotes the preference relation of voter i. Unlike eqn [1], the $\succsim_i$ are primitive relations not derived from $\succsim$, and $\succsim$ takes the role of a social preference relation which is a function of the voter preference profile $(\succsim_1, \ldots, \succsim_n)$. Conditions of order, fairness, positive responsiveness, and so forth, can then be proposed to relate $\succsim$ to realizations of $(\succsim_1, \ldots, \succsim_n)$. Some sets of conditions lead to additive representations for simple majority, weighted majority, and more general rules, whereas others are collectively incompatible (Arrow, 1963) and result in impossibility theorems.

Decision Under Risk and Uncertainty

Conjoint measurement is used extensively for multi-attribute outcomes in decision under risk and uncertainty (Keeney and Raiffa, 1976). Consider the expected-utility representation

$$p \succsim q \Leftrightarrow \sum_{x \in X} p(x)u(x) \geq \sum_{x \in X} q(x)u(x) \qquad [5]$$

where p and q are simple probability distributions on $X = X_1 \times \ldots \times X_n$ and u on X is unique up to a positive affine transformation $au + b$, $a > 0$. Let p_i be the marginal distribution on X_i of p. The independence condition which says that $p \sim q$ whenever $p_i = q_i$ for all i implies an additive decomposition $u(x_1, \ldots, x_n) = u_1(x_1) + \ldots + u_n(x_n)$ for outcome utilities (Fishburn, 1970: p. 149). A less-restrictive condition says that, for every i, the preference order over marginal distributions on

X_i at fixed values of the other attributes is independent of those fixed values. This implies either the additive decomposition or a multilinear form which under somewhat stronger conditions can be expressed as

$$ku(x_1, \ldots, x_n) + 1 = [ku_1(x_1) + 1] \ldots [ku_n(x_n) + 1] \qquad [6]$$

where k is a nonzero constant. A number of other decompositions of u are also described in Keeney and Raiffa (1976).

Abstract

This article reviews the evolution and development of conjoint analysis (CA) applications and their similarities, differences, strengths, and weaknesses. Traditionally, CA used experimental designs to vary levels of attributes/features hypothesized to underlie decisions and to create combinations of factor levels (e.g., a bus trip of 30 min with service every 15 min at $2, or a trip of 15 min at $2.75). Subjects evaluate each designed combination holistically in category rating or ranking tasks; their responses are decomposed by statistical analysis, typically using general linear statistical models. More recently, methods based on random utility theory have been developed and applied. These new methods use experimental design techniques not only to vary attributes and levels but also to create choice sets from which subjects select one option. Choices are decomposed using discrete multivariate statistical models. Very recently, theoretical links between choices in experiments and in real settings have been derived and investigated, and several empirical tests suggest that these links hold to a close first approximation. Additionally, comparisons of experimental and other 'stated' choices suggest that these theoretical links can be extended to many preference data source comparisons.

Introduction

This article provides a general discussion of conjoint analysis (CA) applications and identifies and reviews principal contributions, streams of research, and applications within the overall field. CA is a generic term for methods developed to model and measure preferences and trade-offs that share several common features:

(a) independent variables or 'attributes' that explain preferences are identified and defined (e.g., bus travel times and fares; MHz and prices of PCs);
(b) attribute 'levels' relevant to the research are assigned (e.g., 30, 60 min travel time or $1, $3 fare for buses; 600, 733 MHz and $2500, $2850 prices for PCs);
(c) statistical design techniques are used to combine the attribute levels and create descriptions of options (e.g., 15 min travel time for $2 or 733 MHz for $2850);
(d) a sample of individuals evaluate all or a subset of the descriptions;
(e) individual- or group-level models are estimated from the evaluation data (e.g., transport modes or PC options); and
(f) the estimated models are used to measure subjective quantities (e.g., the subjective value of 600 vs. 733 MHz or implied willingness to pay to save 30 min travel time).

Despite commonalities, CA methods also differ in experimental designs, response tasks, model form(s), and measurement of subjective quantities. For example, initial CA applications were based on an axiomatic theory of the behavior of a ranking of all possible combinations of a discrete set of attribute levels (e.g., Krantz and Tversky, 1971). All possible combinations of attribute levels are given by complete factorial enumeration, such that if $A_1(I)$, $A_2(J)$, …, $A_n(N)$ represent the number of levels of attributes 1, 2, …, N, then all combinations are given by the expression $I \times J \times \ldots \times N$. Thus, in a full factorial experiment the total combinations equal the product of the levels of each attribute. For example, if the attributes (levels) are bus fare (3), travel time (3), and service frequency (3), then there are $3 \times 3 \times 3$ (or 3^3) $= 27$ possible bus descriptions.

If a subject ranks all designed descriptions in order of preference (or another subjective dimension), and certain axiomatic conditions are satisfied, the ranking can be represented by an algebraic model defined by marginal and joint attribute effects. For example, for two or more factors, a ranking of a factorial set of options is additive in the attribute effects, if, and only if, the effects of all attributes on the ranking are independent of one another and there are no joint attribute effects (i.e., only marginal effects apply). That is, an additive process underlying a ranking of all combinations of, say, the ith, jth, and kth levels of attributes A_{1i}, A_{2j}, and A_{3k}, respectively, can be expressed as:

$$V_{ijk} = c + \upsilon(A_{1i}) + \upsilon(A_{2j}) + \upsilon(A_{3k}) \qquad [1]$$

where V_{ijk} is the overall value of attribute level combination ijk, c is a constant that sets the response scale origin and $\upsilon(A_{1i})$, $\upsilon(A_{2j})$, and $\upsilon(A_{3k})$ are values of the ith, jth, and kth levels of each attribute.

Statistically, if the underlying process is additive, all attribute interactions will be nonsignificant. If the underlying process is multiplicative, the model is as follows:

$$V_{ijk} = c^* + \upsilon(A_{1i})\upsilon(A_{2j})\upsilon(A_{3k}) \qquad [2]$$

where all terms were previously defined, except c^*, a constant to set the scale origin. Equation [2] requires all attribute main effects and interactions to be significant. Early applications lacked error theories, hence used goodness-of-fit tests to evaluate and compare models.

Full factorial designs proved too large, so ways to reduce numbers of combinations were proposed, such as fractional or other partial factorial designs, ranking all pairs of attribute levels or using incomplete block designs to select attributes and levels (e.g., Green, 1974). Most applications rely on non replicated fractional factorials that cannot be used to test model

forms and produce few observations relative to parameters for individuals (Louviere, 1988). However one can estimate individual models if response, design, and model assumptions are satisfied (e.g., equal interval response scales, insignificant interactions, independent and identically distributed normal errors).

A new paradigm emerged when McFadden (1974) developed computationally tractable extensions of random utility theory (RUT) to the multiple-choice case. This provided ways to estimate and test choice models with a formal theory of errors based on RUT. RUT assumes an unobservable value, U_i, for each of $i = 1, 2, \ldots, I$ options that is a sum of observable (explainable) and random (unexplainable) components:

$$U_i = V_i + \varepsilon_i \quad [3]$$

where V_i and ε_i are, respectively, observable and random components. RUT assumes that individuals try to choose their preferred options, but the random component implies that choices are inherently stochastic from a researcher's perspective: that is, the probability that a subject will choose an option from a set of options is predictable, not the exact choice. If $P(i|C)$ is the probability of choosing option i in set C, and Max = maximum operator, then

$$P(i|C) = P[(V_i + \varepsilon_i) > \mathrm{Max}(V_j + \varepsilon_j), \text{ for all } j \text{ options in } C] \quad [4]$$

Different discrete choice models are derived by making assumptions about the distributions of the ε's. For example, McFadden (1974) derived the multinomial logit model (MNL) by assuming that the ε's were independently and identically distributed Gumbel random variates. MNL choice probabilities have a simple closed-form, but if the ε's are non-independently and identically distributed normals, the nonclosed form multinomial probit (MNP) model results.

Louviere and Woodworth (1983) integrated RUT-based choice models with CA, and proposed ways to design choice experiments consistent with RUT-based choice models. This choice-based (CB) approach designs attribute level combinations (to estimate evaluation/utility functions) and selects choice sets in which they appear (to satisfy properties of choice models), and the error theory is used to select and test model forms. The CB approach typically estimates models from samples of subjects because individuals provide too few observations to satisfy asymptotic theory and obtain reliable model estimates.

Choice experiments mimic real choice situations. For example, to model choice of travel mode to work, one designs experiments to offer commuters sets of mode choices; to model choice of health insurance plan, one designs experiments that offer subjects sets of health insurance options. Thus, the CB approach designs attribute level combinations to describe sets of options (say M of them). If $M = 1$, subjects evaluate each option separately, making Mbinary choices (e.g., will/will not choose); if $M > 1$, subjects evaluate sets of multiple options (say S of them), making S multiple choices (Louviere and Woodworth, 1983; Louviere et al. 2000).

Significant progress has been made in linking behavior in choice experiments and real environments. Specifically, in RUT models the magnitude (or 'scale') of the parameters are inversely proportional to choice variability. For example, if we denote the scale as λ, it can be defined as follows for MNL models (Ben-Akiva and Lerman, 1985 : 104–105): $\lambda^2 = \pi^2/6\sigma_\varepsilon^2$ (π is the natural constant; σ_ε^2 = error variance). In empirical applications, analysts estimate the quantities $\lambda\beta_k$, not β_k (β_k is a k-element parameter vector associated with design matrix, X_{ki}, and the ith choice option).

Thus, λ is not identified in any one data source, and typically is set equal to one for convenience. Ben-Akiva and Morikawa (1990) showed that ratios of λ's can be identified and estimated from two or more choice data sources; hence, if experimental and actual choices differ only in response variability, parameters estimated from each will be proportional. Empirical tests in several fields suggest that parameter proportionality often holds to a close first approximation (see Louviere et al. 1999).

This property of RUT-based choice models allows many sources of preference and choice data to be compared, including traditional CA data. For example, one can transform CA ranks into implied choice sets by 'exploding' subjects' complete or partial orders into one or more choice sets (Louviere et al. 2000). That is, for a ranking of M options, the first is preferred to the other M–1, the second to the remaining M–2, etc; hence M rankings yields M–1 choice sets (if A, B, C, D are ranked 1, 2, 3, 4 the first set contains A, B, C, D with A chosen; the second set contains B, C, D with B chosen; etc). Such explosions transform preference responses into discrete choices that can be compared using RUT-based statistical models (e.g., Louviere et al. 2000). Recently Bayesian methods have been used to estimate individual-level parameters (Wedel et al. 1999), but the pros and cons of these methods in CA and CB applications have not been fully explored.

Statistical properties of choice experiments also remain elusive. In particular, humans interact with CA and choice experiments and particular designs can impact response variability. Statistically efficient designs may require many choices, which may increase choice variability; increases in choice variability may offset higher statistical design efficiency. Hence, research into behavioral impacts of designs and effects of non design issues like task layouts, formats, response tasks, etc, on choice variability also are needed.

Abstract

Measurement theory is the attempt to understand scientific measurement. It is at least as old as Euclid's *Elements*, where concepts basic to the classical understanding are defined. At first the classical concept applied only to extensive quantities, but in the Middle Ages it was expanded to include intensive quantities. It was further developed to include the concepts of unbounded, continuous quantity and fundamental, derived, and conjoint measurement, all of which raised questions about practices called 'psychological measurement.' The classical concept was later challenged by representational and operational concepts, but it still dominates within the paradigmatically quantitative sciences.

Measurement theory is the attempt to understand scientific measurement. Quantitative concepts and methods infuse the entire corpus of modern physical science. The presumption that physics is the methodological touchstone for science led psychologists to propose their own, special methods intended to measure psychological attributes. After a century or more, the issue of whether these methods deliver measurement, in the scientific sense, remains open. Critical scrutiny of psychological methods requires a theory of measurement matching the realist, cognitive aspirations of science. Such a theory evolved over the past two and a half millennia in tandem with developments in quantitative physical science, but has been influenced also by nonrealist philosophical fashions. The vicissitudes of this evolution constitutes the subject matter of the history and philosophy of measurement theory. The following sketch tracks some main lines of this evolution.

Measurement Theory and the Development of Quantitative Physics

Extensive Magnitudes and Real Numbers

The practice of measuring quantitative properties by counting units was a ubiquitous feature of all early human societies (Morley and Renfrew, 2010). Out of this practice, the problem of incommensurability became clear to ancient Greek scientists. Book V of Euclid's *Elements* (Heath, 1908), compiled around 300 BC, resolved this problem by redefining the fundamental metrological concept of ratio. The resulting understanding of measurement remains standard today.

The ancient Greeks distinguished discrete quantity (e.g., the size of a football crowd) from continuous quantity (e.g., the length of a stadium), measures in each case being assessed via numbers of appropriately defined units. Number, then, was what is now called 'whole number.' The problem of incommensurability is that two different magnitudes of a continuous quantity may be such that the size of one relative to that of the other does not equal a ratio of whole numbers (e.g., the lengths of the side and diagonal of a square). This seemed to imply that some magnitudes are not measurable relative to some units.

The solution to this problem lay in liberalizing the concept of ratio. First, two magnitudes are "said to have a ratio to one another which are capable, when multiplied, of exceeding one another" (Heath, 1908, p. 114). That is, any two lengths, say L_1 and L_2, where $L_1 \leq L_2$, have a ratio because there exists a whole number, n, such that $nL_1 > L_2$. Then, any two lengths (call them L_i and L_j) are said to be in the same ratio as another pair (L_h and L_k) if and only if for each pair of whole numbers, n and m,

$nL_i < mL_j$ if and only if $nL_h < mL_k$;
$nL_i = mL_j$ if and only if $nL_h = mL_k$; and
$nL_i > mL_j$ if and only if $nL_h > mL_k$.

This definition allows incommensurable pairs of lengths to stand in the same ratio, and while this ratio does not equal a ratio of two whole numbers, the ratio of any such incommensurable pair, L_i and L_j, is uniquely specified by the class of all whole-numbered ratios, n/m, where $nL_i \leq mL_j$. Of course, the ancients did not recognize such classes as identifying numbers, as Dedekind (1872) did when he later defined the concept of a real number, but Dedekind's definition was deeply indebted to Euclid (Stein, 1990). As far as measurement is concerned, when a magnitude is incommensurable with the unit employed, the ratio between them always falls between ratios of whole numbers and, so, can always be estimated to any level of accuracy. This liberalized concept of ratio generalizes to any continuous quantity admitting multiples of magnitudes, which the ancients took to include extensive quantities such as weight, time, and the geometric magnitudes. It implies the classical concept of measurement, viz., that measurement is the estimation of the ratio between a magnitude of a quantity and a unit of the same quantity.

Intensive Magnitudes and the Concept of Continuous Quantity

The ancients recognized that nonextensive attributes (e.g., temperature) admitted of different degrees and sometimes discussed these in terms of ratios (e.g., Aristotle (1941)). However, medieval philosophers like Duns Scotus (Cross, 1998) seem to have been the first to seriously consider the idea that some nonextensive attributes might actually possess the same kind of structure as extensive quantities and, so, be measurable in exactly the same sense.

Euclid's *Elements* (Definitions 3 and 4 of Book V) taught that the class of magnitudes constituting an extensive quantity are homogeneous in the sense of being all of the same kind, but had used the idea of extensive multiplication as the criterion of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43062-X

homogeneity. Duns Scotus, thinking in terms of changes from 1° or intensity of a quality to another, understood homogeneity in relation to differences: the degrees constituting a quality are homogeneous when the differences between them are all of the same kind and do not differ qualitatively, and the attribute is quantitative if the degrees differ from one another only quantitatively. Such an attribute is an intensive quantity, and while its internal quantitative structure is not manifest via operations of extensive addition and so it is not measurable by procedures analogous to extensive quantities, it is nonetheless measurable, in principle, because, as Oresme put it, "whatever ratio is found to exist between intensity and intensity, … a similar ratio is found to exist between line and line and vice versa" (Clagget, 1968, p. 167).

While medieval philosophers successfully freed the concept of quantity from its ancient exclusive attachment to extensive attributes, they were never successful in finding ways to measure attributes that they thought of as intensive quantities. Attempts to expand the range of measurable attributes were more successful from the Scientific Revolution of the seventeenth century onward, when science became more closely identified with quantitative methods. Such attempts raised another problem: it was one thing to introduce the possibility of intensive magnitudes theoretically; it was quite another to have evidence showing that a putative intensive quantity really was quantitative.

Most of the attributes found to be measurable from the seventeenth century onward are not extensive and are measured only indirectly via other quantities. For example, velocity is measured via distance and time, and density via mass and volume. The magnitudes measured in this derived way were thought of as quantitative attributes of the objects or systems involved, but ones for which no physical operation directly reflecting the attributes' underlying additive structure had yet been identified. Because quantitative physics was thought to provide a model for aspiring sciences, other disciplines aped its quantitative character. For example, Hutcheson (1725) proposed a quantitative moral psychology, but was criticized by Reid for "applying measures to things that properly have not quantity" (1948, p. 717), a charge that was to become increasingly familiar in the nineteenth century as psychologists attempted to quantify mental attributes.

The problem of how to distinguish quantitative from nonquantitative attributes required for its solution an explicit specification of quantitative structure. Helmholtz (1887) made a first attempt, which in turn inspired Hölder (1901) to successfully define the concept of an unbounded, continuous quantitative attribute, that is, the kind of attribute presumed in quantitative physics. Letting Q stand for any attribute, $a, b, c, \ldots$, etc., for any magnitudes of Q, and allowing that the expression $a + b = c$ is true if and only if c is entirely composed of discrete parts a and b, then Q is an unbounded, continuous quantity if and only if

1. Given any two magnitudes, a and b of Q, one and only one of the following is true:
   (i) a is identical to b (i.e., $a = b$ and $b = a$);
   (ii) a is greater than b and b is less than a (i.e., $a > b$ and $b < a$); or
   (iii) b is greater than a and a is less than b (i.e., $b > a$ and $a < b$).
2. For every magnitude, a of Q, there exists a b in Q such that $b < a$.
3. For every pair of magnitudes, a and b in Q, there exists a magnitude, c in Q such that $a + b = c$.
4. For every pair of magnitudes, a and b in Q, $a + b > a$ and $a + b > b$.
5. For every pair of magnitudes, a and b in Q, if $a < b$, then there exist c and d in Q such that $a + c = b$ and $d + a = b$.
6. For every triple of magnitudes, a, b, and c in Q, $(a + b) + c = a + (b + c)$.
7. For every pair of classes, ϕ and ψ of magnitudes of Q, such that
   (i) each magnitude of Q belongs to one and only one of ϕ and ψ,
   (ii) neither ϕ nor ψ is empty, and
   (iii) every magnitude in ϕ is less than each magnitude in ψ,
   there exists a magnitude x in Q such that for every other magnitude x' in Q, if $x' < x$, then $x' \in \phi$ and if $x' > x$, then $x' \in \psi$ (depending on the particular case, x may belong to either class).

If an attribute has this kind of structure, the system of ratios of its magnitudes is isomorphic to the system of positive real numbers, which entails that each magnitude of the attribute may be measured by any other magnitude taken as the unit of measurement. Hence, Hölder's seven conditions adequately characterize the kind of measurable attributes found in the physical sciences and nicely rounds out the classical concept of measurement.

The issue could now be considered of the sort of evidence needed to confirm the hypothesis that some attribute is quantitative. If, relative to any attribute, it is possible to identify a concatenation operation directly reflecting the attribute's additive structure, then evidence of quantitative structure may be obtained. For example, rigid straight rods may be joined so that the resulting length equals the sum of the lengths concatenated. Campbell's (1920) term "fundamental measurement" is widely used to describe this way of establishing that an attribute is measurable.

Campbell also identified 'derived measurement.' For example, the ratio of mass to volume is a different constant for each different kind of substance, say, one constant for gold, another for silver, and so on. Taking such constants to identify magnitudes of a quantitative attribute is sound scientific reasoning. In the case of density, for example, the fact that such a correlation between constants and substances is always observed requires that each different substance possesses a different characteristic as its basis, and the fact that the constants are quantities means that this basis must likewise be quantitative. A similar line of thought applies to all cases of indirect quantification in physics.

Campbell (1920) thought that physics was, by definition, "the science of measurement" (p. 267) and concluded that evidence for quantitative structure was exhausted by his categories of fundamental and derived measurement. He did not know that Hölder (1901) had earlier given a counterexample to this view using a simple model. Consider the set of all intervals between points on a straight line. If all that is known of any two intervals were whether they span equal distances, would this be sufficient to prove that distance is a quantitative attribute?

Hölder proved yes, exploiting the fact that some intervals are completely nested within others and the distance spanned by any interval always equals the sum of the distances spanned by the discrete intervals nested within and constituting it. His result displays that there are ways over and above fundamental and derived measurement of showing attributes to be quantitative. Hence, the possibility of measuring nonphysical attributes (such as psychological attributes) cannot be ruled out a priori, as Campbell insisted.

Measurement of Psychological Attributes

There are no fundamentally measurable, extensive psychological attributes upon which to base the enterprise of psychological measurement. Thus, attempts to gain evidence that psychological attributes are quantitative cannot utilize Campbell's categories of fundamental and derived measurement. However, Hölder's counterexample illustrated the fact that alternatives are possible, and Luce and Tukey (1964) introduced one to the psychological literature, viz., conjoint measurement theory (see article Measurement Theory: Conjoint). This theory applies in circumstances where a first attribute is a noninteractive function of a second and third attribute, such that distinct levels of the second and third can be identified and classified as the same or different and levels of the first attribute at least weakly ordered. Since, in psychology, such classifications and orderings of levels of attributes are sometimes possible, this theory promised to resolve the issue of evidence regarding whether psychological attributes are quantitative. If the attributes involved are quantitative, then this may be discernable via trade-offs between the contributions of the second and third attributes to order relations between levels of the first. This theory also made explicit the need for such evidence in every case of quantification by revealing the fact that derived measurement in physics is never a matter of mere definition, as, for example, Carnap (1966) had suggested was the case for density measured via mass and volume, but always depends upon empirically testable propositions.

While conjoint measurement has been applied in psychology (see article Measurement Theory: Conjoint Analysis Applications), it is most often employed as a scaling device (on the assumption that the relevant attributes are quantitative), rather than as a diagnostic tool for testing this assumption. In the best case scenario, the theory of conjoint measurement would allow the conjecture that some attribute is quantitative to be demonstrated via construction of 'standard sequences' (Krantz et al., 1971). In this way, the character of the putative additive structure hypothesized within psychological attributes could be articulated. Otherwise, the quantitative structure presumed of such attributes remains an empty speculation.

From the time of the first serious attempts at psychological measurement (Fechner, 1860), reservations were expressed about whether such attributes possess additive structure or even satisfy the requirement of possessing the necessary kind of homogeneity (e.g., Tannery, 1875). As Tannery and others (e.g., von Kries, 1882) noted, if differences between degrees of an ordered attribute are of different kinds (i.e., not entirely homogeneous), then the attribute cannot be quantitative. This is because differences between its degrees are not naturally ordered and, so, cannot satisfy even Hölder's condition (1).

However, while this kind of objection was taken seriously in other disciplines (e.g., Keynes, 1921), in psychology it was never seriously considered and, instead, the 'psychometricians' fallacy' (Michell, 2009) was endorsed: viz., the conclusion that, if an attribute is ordered, then it must be quantitative (e.g., Titchener, 1905). Consequently, psychological 'measurement' (so-called) involves attributes that have never been shown to possess an additive structure and, in some cases, attributes that appear to lack the required kind of homogeneity (Michell, 2013).

Measurement Theory and Issues External to Quantitative Science

Philosophy of Mathematics

A potent external factor influencing measurement theory is the philosophy of mathematics. Hölder's conclusion of an isomorphism between ratios of magnitudes of a continuous quantitative attribute and the positive real numbers secured the view, popular at least since Newton (1728/1967) that the numbers are such ratios, a view articulated in detail by Frege (1903) and Whitehead (Whitehead and Russell, 1913). However, consistent with the modernist transformation that sought to separate the subject matter of mathematics from that of the empirical sciences (Gray, 2008), other philosophers attempted to divorce the concept of number from that of quantity (e.g., Russell, 1897). The view that dominated thinking in the twentieth century was that numbers are 'abstract entities,' that is, they exist only outside space and time (Bostock, 2009). As a result, measurement was no longer understood in the classical manner as the estimation of ratios of magnitudes because such ratios were no longer identified with real numbers. Instead, measurement was redefined as the representation of objects and relevant relations between them by numbers and numerical relations, the numbers themselves being understood as existing outside of the empirical context of measurement and only introduced as a tool (Russell, 1903; Campbell, 1920; Nagel, 1931; Ellis, 1966; Krantz et al., 1971; Suppes et al., 1989; Luce et al., 1990; Narens, 2002) (see article Measurement, Representational Theory of).

According to Luce and Narens (1994), the representational approach to the measurement of any attribute reduces to four steps:

First, an empirical structure, involving an observable set of objects and a finite number of empirical relations in which they stand, is identified.

Second, a set of axioms characterizing this empirical structure is specified. As far as possible these should be empirically testable.

Third, an abstract numerical structure is identified such that a set of many-to-one mappings (homomorphisms) between the empirical structure and this numerical structure can be proved from the axioms (the 'representation theorem').

Fourth, a specification of how the elements of this set of homomorphisms relate to one another is given, generally by identifying the class of mathematical functions that

includes all transformations of any one element of this set into all other elements (the 'uniqueness theorem'). This allows the distinctions between scale types, earlier popularized by Stevens (1951), to be precisely defined.

Expressed in this mathematically sophisticated version, the representational theory of measurement attempts to assimilate the concept of measurement to the theory of numerical representations. As has been pointed out, however (Mundy, 1994; Michell, 2007a), understood in representational terms, quantitative theories in physics would require something very like Hölder's (1901) concept of continuous quantity as the empirical structure to be numerically represented, which entails that something having the structure of the system of positive real numbers (i.e., the system of ratios of magnitudes) is already present in the empirical structure. The idea that such ratios of magnitudes are numbers is implicit within the classical theory of measurement (Michell, 1994). This kind of empirical realist view of number fits with the more general thesis that mathematics is the general science of structure (i.e., both empirically instantiated and empirically unrealized structures), and it avoids the difficulties encountered in attempting to construe numbers as 'abstract entities,' not the least of which is the issue of how, as such, they could ever be known by us. Recently, philosophies of mathematics that locate numbers in the empirical contexts of their application have reappeared (Franklin, 2009).

Philosophy of Science

The philosophy of science has also influenced measurement theory. In relation to the understanding of measurement in psychology, the most significant philosophical influence during the twentieth century was operationism (Bridgman, 1927). If, as Bridgman maintained, the meaning of any concept is the set of operations used to identify it, then measurement is the 'assignment of numerals to objects or events according to rules' as Stevens (1951, p. 1) defined it. Operationism was adopted because it seemed an *avant-garde* philosophy promising to bring psychology into line with physics, but ironically and despite its enduring popularity, this definition of measurement does not match that still standard in physics (Michell, 2007b). First, as measurement is understood in physics, it makes no sense to talk of measuring 'objects or events' unless it is attributes of such things that are being considered. Attributes (i.e., properties of things or relations between things) are always the object of measurement. Second, while 'numerals' (i.e., the names of or signs for numbers) are generally present in most acts of measurement, this is only because measurement involves reference to numbers as ratios of magnitudes. It is always numbers that are identified in measurement in the first instance and numerals, only secondarily. Third, in measurement, numerals are no more 'assigned' to anything than in, say, describing colors, color words are assigned to things. Just as a description via color words attempts to express a fact, so an act of measurement attempts to describe a quantitative fact, and making a description is never a matter of assigning one thing to another. Fourth, according to Stevens' definition, there is nothing that cannot in principle be 'measured' because numerals can always be assigned to anything according to some rule or other. However, according to the understanding current in physics, the only measurable attributes are those having the kind of structure that sustains ratios (i.e., quantitative structure). If the aim was to bring the understanding of measurement in psychology into line with that in physics, Stevens' proposed definition represents an intellectually self-defeating maneuver, which, because it encouraged the use of the term 'measurement' for practices not falling under that predicate, alienated psychology from the traditions of quantitative science.

Michell's (1999 and 2007b) works contain further material on the history and philosophy of measurement theory in psychology and social sciences.

Mechanism-Based Causal Analysis

Abstract

Over the past decades, 'causal mechanisms' have become an important part of social scientific explanation. Causal mechanisms now appear in annual review pieces, edited volumes, and occasional symposia. The publication of the *Oxford Handbook of Analytic Sociology* – a manifesto of the analytic paradigm that places mechanisms at the helm of its enterprise – is further evidence of this new focus. But what, precisely, are causal mechanisms? And how do they aid in explanation in the social sciences? This article investigates five major approaches to causal mechanisms toward the goal of identifying major points of consensus and contention. It further suggests that there are two distinct approaches to causal mechanisms: 'top-down' approaches that seek to generalize empirical events under widely instantiated causal patterns, and 'bottom-up' approaches that seek to disaggregate 'average causal effects' by opening up the 'black-boxes.'

Introduction: Mechanisms and Explanation in the Social Sciences

Over the past decades, 'causal mechanisms' have become an important part of social scientific explanation. Causal mechanisms now appear in annual review pieces, edited volumes, and occasional symposia. The publication of the *Oxford Handbook of Analytic Sociology* – a manifesto of the analytic paradigm that places mechanisms at the helm of its enterprise – is further evidence of this new focus. But what, precisely, are causal mechanisms?

There are plenty of answers to this question but no clear consensus. James Mahoney (2001), for instance, has cataloged some 24 variants. Doug McAdam, Sidney Tarrow, and Charles Tilly remark that "no conceptual, theoretical, or methodological consensus has so far emerged" (2008: 308). Similarly, Neil Gross notes that even though "a clear definition is an essential first step towards a sociological theory of mechanisms … confusion abounds as to what exactly a mechanism is" (2009: 359).

The rising appeal of mechanistic explanation on the one hand, and the intensifying disagreement over the nature of that enterprise on the other hand, has been a source of tension in the literature. Some have worried that this lack of coherence prevents theory building. Others have questioned the usefulness of this vague and contested explanatory tool. What is at stake in this debate, then, is whether causal mechanisms have the potential to be a foundation for a unified approach to social science, or whether debates over mechanisms are likely to remain unresolved.

This article of the literature argues that, to an extent, both conclusions are tenable. That is, underlying many of the competing approaches to causal mechanisms lies a core conceptual consensus upon which a unified approach to social science is being built. This consensus revolves around the notion of mechanisms as 'generalized causal chains that produce an effect.' Debates over mechanisms can thus be understood, as John Gerring (2007) argues, not as debates over the nature of mechanisms but rather as debates over which subtypes of mechanisms are important to social science. While competing research agendas drive scholars to privilege different mechanism subtypes, many (though, importantly, not all) of these competing accounts are largely compatible with the minimal concept of a mechanism provided above. This is a cause for optimism. To the extent that debates over mechanisms can be recast as elaborations of subtypes rather than as irreconcilable views on the very nature of mechanisms, mechanisms can be a basis for a unified social-scientific logic of inquiry.

However, there are at least two reasons that mechanism debates are unlikely to be wholly resolved anytime soon. The first is salutary. A plurality of mechanism accounts may simply be the product of the success of the concept. Because mechanisms are so broadly applicable, further specification is necessary, even for those accounts that have a unified conceptual core. That is, researchers must go beyond considering the nature of mechanisms and actually locate mechanisms in the empirical world. Mechanism subtypes give guidance; for instance, rational choice mechanisms provide a more analytically powerful theoretical lens than 'mechanisms' as a general concept. That these subtypes simultaneously provide theoretical guidance and generate theoretical tension means that we should neither expect nor desire a single mechanisms approach.

The second reason for the continuing debate over mechanisms reflects a deeper disagreement, however, and therefore raises the possibility that there are two irreconcilable approaches to mechanistic explanation. This is the case because not all approaches can be considered subtypes of a conceptual core that views mechanisms as generalized causal chains that produce effects. The source of disagreement is the requirement of 'generalized' explanation: While one notion of mechanisms relies upon a theory of explanation based on generalization or unification (i.e., mechanisms explain by subsuming a phenomenon under some widely instantiated, robust causal pattern), a second notion relies upon a view of explanation more akin to opening a black-box (i.e., mechanisms explain by identifying contextually specific chains of causation that may be neither robust nor generalizable). Theorists in the second camp would not require that mechanisms be generalizable. In fact, they would laud the explanatory content of the specific. By contrast, theorists in the first camp would hold that removing 'generalizable' from the concept violates the core premise of mechanistic explanation, and perhaps of explanation more generally. Whether differences between these camps implies

that there exist two distinct notions of mechanisms remains an open question, but it is one worth exploring as the literature on mechanisms progresses.

This article provides an extended review of the literature on mechanisms and an assessment of its main points of contention. This article proceeds as follows: Part II presents a review of five major theoretical accounts of causal mechanisms; Part III assesses the principal areas of contention; and Part IV concludes.

The Many Meanings of Mechanisms

Before delving into the various approaches to mechanisms, it will be helpful to ask whether it is worth searching for conceptual consensus. How big a problem is it to have different accounts of mechanisms? Might there not be a benefit to using ambiguous concepts? After all, it is perhaps no more realistic or desirable to come up with a unified definition of a causal mechanism than it is to come up with a unified definition of democracy or culture. Moreover, as stated above, there are good reasons for disharmony. Mechanisms operate differently in different domains: Because biological, historical, and psychological mechanisms refer to different content, we should not expect to come up with a universally satisfying conceptual definition (Kuorikoski, 2009). Distinct definitions allow for the mutual recognition of our similar projects and the cross-fertilization of ideas, without the impossible requirement that theory building come after a clear definition has been settled upon. Second, the fact that there are many approaches to mechanisms may overstate the degree of confusion in the field. While the debate over mechanisms may evince deep disagreement, if put upon to provide a mechanism for a given relationship, most social scientists will understand what they are being asked to do.

However, the fact that there are good reasons for theoretical proliferation does not mean that the literature on mechanisms should stop exploring whether various approaches rest upon a shared conceptual foundation. Quite the opposite. Over the last few decades, debates over mechanisms have served as one of the important arenas in which social science has considered, stipulated, and debated its goals. Clarity on these goals is essential to justifying the kinds of endeavors social science is engaged in and for articulating – to ourselves as much as to outsiders – why the sort of information it provides is important. Calls for clarity on mechanisms are in essence calls for clarity on social science's understanding of its explanatory endeavors and thus are crucial to the development of a coherent logic of inquiry. For this, we need not be worried that there are different subtypes of mechanisms, but we certainly should be concerned if it turns out that mechanisms evince a deeper form of conceptual plurality in which the single term masks distinct approaches to explanation. Below, I explore five major accounts of mechanisms to analyze the extent to which mechanisms evince theoretical plurality in their approaches to explanation, as well as the extent to which these different approaches are engaged in a single, coherent endeavor.

What Mechanisms Are Not: The Hempelian View

Many accounts of mechanisms see themselves as responding to a view of the social sciences as engaged in the endeavor of discovering 'social laws.' Articulated by Carl Hempel, this view, known as the covering-law model of explanation, argued that the explanation of an event consisted in developing its description into a series of premises, at least one of which contained a lawlike statement (Hempel and Oppenheim, 1948). For example, I can explain why my door is difficult to open in the summer by deriving the following premises: (1) my door is made of wood; (2) wood expands in heat; and (3) summer is hot. Hempel contended that explanations of human behavior were fundamentally similar to these sorts of physical phenomena. Logical positivists (with whom Hempel is typically associated, though he rejected that term) thus root explanation in the identification of constant conjunctions of events. They reject the notion that knowledge could come from anything other than direct sensory experience and consequently take the antirealist stance of rejecting the existence of theoretical or unobservable entities.

Hempel's covering law approach proved influential but critics soon rejected it. They argued that explanation by 'constant conjunction' provides 'no understanding' (Bunge, 1997), a criticism perhaps even more damning than the charge that social laws, as opposed to physical laws, did not, in fact, exist (Hedström and Swedberg, 1998). Most importantly, Hempel's antirealist stance was anathema to social scientists who considered their object of study, society, to be both a real and a theoretical entity (Steinmetz, 1998).

In short, the 'covering law' approach to explanation has now been largely rejected by social theorists. Nevertheless, most contemporary accounts of mechanisms have this view in mind when articulating the explanatory advantages of the mechanistic approach.

Critical Realism

The critical realist approach to social science, associated with Roy Bhaskar, identifies the very purpose of social science as the search for causal mechanisms. Rejecting the antirealism of both logical positivism and postmodernism, Bhaskar motivates the existence of causal mechanisms by asking the question: 'What must be true about the world in order for science to be intelligible?' (Bhaskar, 1978; Steinmetz, 1998). Bhaskar's answer is that the scientific method indicates the existence of real causal mechanisms. First, empirical generalities in the real world are a rarity. Instead, science has to engineer 'constant conjunctions' in controlled, laboratory experiments ('closed systems'). Because constant conjunctions are artificial productions, they should not, as positivism argues, form the basis of explanation. However, even though constant conjunctions must be engineered, the relationships identified within closed systems successfully predict events outside the laboratory (within 'open systems'). This forces us to also reject postmodernism's claim that the objects of inquiry in science are mere theoretical creations, without real referents. In short, in order for science to be intelligible, there must exist real causal forces that are ontologically distinct from the events that they generate.

Bhaskar (1998[1979]) distinguishes mechanisms from the empirical world by differentiating the world into three hierarchically arranged levels: the 'real,' the 'actual,' and 'events.' Mechanisms refer to a reality separable from both empirical

actuality and perception. They could therefore be at work in a particular context even if they don't produce anything we can observe in the realm of the 'actual.' To see how this is the case, consider the psychological mechanism of an anger management problem: Other mechanisms, such as conformism to societal norms or social ties may mitigate the manifestation of the anger management problem, but this does not negate the presence of the 'real' psychological process underneath.

Bhaskar's causal mechanisms are general and abstract, in the sense that they refer to processes that will be at work in both closed and open systems, and thus exist apart from the context of either the experiment or the empirical world. Finally, for Bhaskar, social scientific explanations would necessarily be different from scientific explanations due to social science's unique objects of inquiry. That is, social structures exist in a meaningful world of concepts and must necessarily engage in hermeneutics to make action intelligible.

Critical realism proved a powerful rejoinder to positivism. Its influence remains evident in nearly all contemporary realist approaches to mechanisms: indeed, while discussions over mechanisms do not always invoke the critical realist approach, the critical realist critique of logical deductivism is often an implicit and essential part of their formulations.

Jon Elster: Mechanisms as 'Cogs and Wheels'

Like Bhaskar, Jon Elster is intent on demonstrating the limitations of the covering law approach. (Elster's views have shifted considerably over the years, and here I focus on his later thought (Elster, 1998, 2007).) Elster argues that general laws are unsatisfactory not because this approach is inappropriate to social reality in any deep, metaphysical way, but rather because uncertainty permeates the social world, undermining the discovery of laws. While ideally we would form laws of the kind 'if p, then q,' uncertainty in initial conditions prevents us from stipulating what 'p' will entail. Elster's concern is that, if we accepted Hempel's account, the lack of identifiable universal laws would result in a purely descriptive social science. Mechanisms provide a solution to this problem by identifying intermediary-level conjectural propositions that explain why 'if p, sometimes q.' As Elster states: 'The "plea for mechanisms" is not an argument against lawlike explanations, only against the idea that when such explanations fail – which they usually do, we must fall back on narrative and description' (49).

On Elster's account, if sufficient evidence could be brought to bear, such that the uncertainty associated with mechanisms could be resolved, mechanisms would, in fact, become laws (Elster, 1989; Persson, 2012). Elster's position thus characterizes mechanisms as an epistemic tool (a feature of our state of knowledge), rather than as a real thing that exists in the world. It therefore constitutes a rupture with realist approaches. Furthermore, his contention that mechanisms be 'easily recognizable,' 'brute' empirical patterns violates the realist position that mechanisms must be conceptually separate from the empirical world. Some theorists associate Elster's focus on empirical generalities and the preference for lawlike explanation with a brand of logical positivism (Norkus, 2005). However, Elster's discussion and examples of mechanisms typically do not feature explanation by deduction nor do they always manifest in empirical regularities (Elster, 1998).

Few mechanism accounts draw upon these more controversial aspects of Elster's definition – the preference for lawlike generalities and the antirealist language (Little, 2013). Instead, Elster's account has primarily been influential due to its intuitive definition ('cogs and wheels') and the incisive delineation of the benefits of mechanisms. However, another aspect of Elster's advantages has been both influential and controversial: the fact that he firmly rooted mechanisms in the reductive strategy of methodological individualism.

As a methodological individualist, Elster holds that: (1) social entities do not exist independently of individuals and (2) social science explanations must cite the individual-level behaviors that give rise to some phenomena (the 'micro-foundations'). Some scholars have argued that it is a mistake to root a definition of mechanisms in methodological individualism (Tilly, 2001), while others have adopted aspects of this brand of methodological individualism (Hedström and Bearman, 2009). However, the rationale for requiring that the conceptual apparatus of mechanisms should reference individual action remains unclear. Most likely, Elster's commitment to methodological individualism has shaped his account of mechanisms, rather than vice versa. If one accepts that explanation must refer to micro-foundations, then so must explanations via causal mechanisms.

Robert Merton and Analytic Sociology

This section combines a discussion of Robert Merton's explication of mechanisms with Hedström and Bearman's discussion of Analytic Sociology, since the latter draws heavily on the former. Though Merton did not develop a full theory of mechanisms, he provided an early and influential definition. Merton (1968) defined social mechanism as 'social processes having designated consequences for designated parts of the social structure.' Social mechanisms and middle-range theories were Merton's antidote for both grand theory and empiricism. Merton anticipated that a more fruitful sociological approach would engage with limited phenomena as these provided an easier route to theoretical advancement. While Merton's critique against grand theory has been powerful and his ideal examples of social mechanisms influential, his account has been criticized as a vague foundation for a positive approach to middle-range theory building (Hedström and Bearman, 2009).

Analytic Sociology begins where Merton left off by further explicating social mechanisms and middle-range theories and placing these concepts at the core of sociological explanation (Hedström and Bearman, 2009). Drawing upon Machamer et al. (2000), they define mechanisms "as constellation of entities and activities that are organized such that they regularly bring about a particular type of outcome" (5). Furthermore, they argue that statistical association is insufficient for explanation: statistical techniques should provide the starting point but not the full content of explanation. For Hedström and Bearman, mechanisms must satisfy two requirements. Firstly, they should be 'semigeneral' in that they should 'make no reference to time, place, identity of actors, content of beliefs, or types of actions' (7). The purpose of abstracting away from

concrete context is that the mechanism should be applicable across a wide range of phenomena. Secondly, mechanisms should refer to the microlevel processes of individual action. For Analytic Sociology, Elster's brand of methodological individualism is softened into 'structural individualism' which gives a nod to the importance of social structure, but maintains that an inextricable link exists between explanation and the elaboration of micro-foundations.

There has been some confusion as to whether Analytic Sociology refers to a type of sociological research or whether it is meant to be a stronger argument for what proper explanation entails (with the implication that explanation not following this approach would be inadequate) (Santoro, 2012). To the extent that it is the latter, there has been pushback to Analytic Sociology's requirement that mechanisms should reference individual-level behavior (Tilly, 2001; Keith Sawyer, 2004).

Finally, further clarification could also be provided as to what 'semigeneral' mechanisms entail. Does a call for semigeneral mechanisms that abstract from place and time imply that mechanisms are, like Hempelian laws, universal? If many of the concepts that govern social life are in flux, then (1) is it indeed more explanatory for mechanisms to be stipulated at this level of abstraction?; and (2) how would a sensitivity to hermeneutics work within this approach? As Analytic Sociology continues to identify its objectives, these ambiguities are likely to require further elaboration.

Mechanisms in Quantitative Methodology

Calls for mechanistic analysis among quantitative researchers hardly represent a single, monolithic view. Nevertheless, a few commonalities can be drawn from some of the more prominent discussions of the estimation of causal mechanisms. Orienting itself against a 'black-box' statistical approach whose goal is the estimation of 'average effects,' this literature argues for the appeal of mechanisms on theoretical as well as epistemological grounds. Average causal effects in and of themselves may not be theoretically interesting parameters (Heckman, 2005). For instance, in the event of heterogenous treatment effects (in which an effect differs by subpopulation), the average causal effect offers only a weighted average, obscuring underlying variation. Morgan and Winship (2007) motivate the need for mechanisms by arguing that "social scientists desire explanations for outcomes that can be modified in straightforward ways when populations shift or contexts change in ways that are separable from the fundamental conditional average causal effects" (224).

There are two points here that differ from the emphasis often provided by theoretical mechanistic accounts. First, it is said that mechanisms, as well as causes, depend upon their social situation; thus, it may be more explanatory to have fine-grained detail about the mechanism's dependence upon context. Second, a key benefit of mechanistic analysis is prediction: knowing how a treatment works will provide information that is transferrable to new contexts.

A separate argument for causal mechanisms concerns their epistemic value. Estimating causal mechanisms may provide a better test of social scientific theories than does the estimation of average causal effects (Morgan and Winship, 2007; Imai et al., 2011). In these cases, the test for mechanisms consists in identifying a variable that represents the mechanistic pathway and in disaggregating the causal effect into direct and indirect pathways (VanderWeele, 2009). Furthermore, estimating mechanisms can provide information that is important for intervention, as mechanisms identify the generative processes that link cause and effect. Barbara Reskin makes this point explicitly in her call for further attention to the mechanisms that give rise to ascriptive inequality (2003). Through mechanisms 'we stand to gain the opportunity to meaningfully contribute to social policy' (17). Finally, mechanisms are useful because they bring additional support to ensure that a statistical relationship is indeed causal (Pearl, 2000). As Pearl demonstrates with the 'Front Door Criterion,' total causal effects can be estimated by stipulating the intermediate variables that link cause and effect.

Overall, the quantitative literature is more concerned with estimating mechanisms than with stipulating their nature. Consequently, it tends to have a more permissive account of mechanisms, identifying them as links within a causal chain, without commitments to generalization, methodological individualism, or a particular theory of action.

Charles Tilly, Mechanisms, and Processes

Charles Tilly (2001), too, promotes mechanisms as an alternative to covering laws. However, Tilly's approach differs markedly from that of Elster and Analytic Sociology in that it does not require that mechanisms refer to individual action. Rather, Tilly argues that individual level 'cognitive mechanisms' are only one of three types of mechanisms (the others being environmental and relational mechanisms).

Tilly identifies the purpose of explanation as unraveling 'episodes,' such as revolution or war, into the mechanisms and processes that generate them. Mechanisms are differentiated from 'processes' in that the former are defined as a 'delimited class of events that change relations among specified sets of elements in identical or closely similar ways over a variety of situations' (25). Processes are essentially concatenations of mechanisms.

Tilly's account provides a view on mechanisms that captures many common aspects of major approaches without the commitment to methodological individualism and with room for relational approaches to social action. Furthermore, his typology of relational, environmental, and cognitive mechanisms is a helpful tool for assessing the sorts of mechanisms that would be present in a full mechanism-account (though Tilly does not argue that mechanism schema must refer to all three types).

However, Tilly's differentiation between mechanisms and processes raises additional questions: if processes are composed of mechanisms, then must mechanisms be 'rock bottom' theoretical entities in that they themselves cannot be further unraveled into submechanisms? A more general point widely applicable to the mechanisms literature concerns the required level of abstraction, such that mechanisms are general enough to be robust across time and place but specific enough to explain the particular 'episode' in question.

Peripheral Debates and the Conceptual Core

These accounts are only a small slice of the literature on mechanisms, which itself is, by all indications, a growth industry. Lest a reader get caught in the weeds, it is helpful to identify some major points of debate. Below, I briefly review three sources of disagreement among the approaches discussed above: micro-foundations, objects of inquiry, and observability.

Micro-Foundations

Many prominent mechanism accounts, including those of Elster and analytic sociologists, posit that mechanisms must be rooted in methodological individualism. In most instantiations of methodological individualism, the fact that social structures can be made explicit in terms of individuals and their relations requires that any acceptable explanation must reference this level of action. As Hedström and Berman explain 'actions are important because all the things that interest us as sociologists are the intended or unintended outcomes of individuals' actions' (9).

However, Tilly (2001) and others have argued that there is little reason for this requirement: 'That intellectual strategy has the advantage of remaining close to the main line of political science explanations and the disadvantage of ignoring a wide range of significant cause–effect connections' (25). For instance, Little (1992) argues that causal–structural explanations, such as the alliance structures among European powers prior to World War II, are perfectly valid without referencing individual-level action. In other words, the position of ontological individualism, the metaphysical position that social facts are composed of individualistic facts, does not entail explanatory individualism, the position that causal explanations must reference those individualistic facts. Moreover, it is often the case that lower-level compositional explanations will provide less satisfying explanations than macro-level ones, since lower-level mechanisms can bring in causally irrelevant material that may be too heterogenous to be explanatory (Jepperson and Meyer, 2011). For example, recognizing that all physical structures are composed of individual molecules does not necessitate that all chemical explanations reference those molecules.

Individual-level mechanisms may certainly be preferred for disciplinary reasons, or may be a part of the research agenda of Analytic Sociology, but these are arguments about the subtypes of mechanisms that we want to identify, rather than arguments about the nature of the mechanisms themselves. As Stinchcombe (1991) argues, levels of analysis should therefore be an empirical, not a doctrinal, issue.

Objects of Inquiry

Some writers have sought to identify mechanisms with a particular theory of action. Neil Gross (2009), for example, views mechanisms as being 'composed of chains or aggregations of actors confronting problem situations and mobilizing more or less habitual responses' (368). Gross' definition draws on his pragmatist orientation that argues that cultural systems and meanings are (1) primary to action, and (2) not reducible to beliefs. This is important for Gross in that Merton and those who draw upon him, do not always include belief systems in their account of action. For instance, Merton's mechanism of 'self-fulfilling prophecies' does not include reference to what it means for actors to hold a particular belief, or the necessary conditions for them to act upon that belief. Other theorists take a very different approach. Elster (2007) identifies mechanism with rational choice. Andrew Abbott (2007), meanwhile, argues that relations, as opposed to individuals, are the important sociological objects of inquiry. (Abbott rejects the mechanistic approach due to its individualist orientation but argues for explanation largely in line with a more permissive account of mechanisms.)

However, it is possible to argue for a certain theoretical approach to mechanisms while not requiring that mechanisms be by their nature rooted in that approach. The explanatory appeal of identifying mechanisms of a certain subtype – pragmatist, rational choice, or relational – is not compromised by recognizing that the nature of mechanisms need not consist in these features.

Observability

Finally, many theorists argue that mechanisms should be considered unobservable theoretical entities. As Gerring (2007) notes, "for many writers, the hallmark of causal mechanisms is their unobservability and hence their hypothetical quality" (166). For example, Mahoney (2001) defines mechanisms as 'posited relations or processes that the researcher imagines to exist; they do not refer to any particular set of empirical conditions' (581); while George and Bennett, quoted in Gerring (2007), argue that 'no matter how far we push the border between the observable and the unobservable, some irreducibly unobservable aspect of causal mechanisms remains' (143). For many, this position is related to the causal realist notion that mechanisms must be differentiated from the causal regularities they generate and cannot be reduced to them.

Still other researchers argue that mechanisms should not be characterized as unobservable; rather, they are simply 'difficult to observe' (McAdam et al., 2008: 308). In fact, for many empirical researchers, the fact that mechanisms produce empirical consequences makes it easier to identify causal relationships by providing evidence of the links between events (Elster, 2007; Pearl, 2000).

Gerring (2007) characterizes this as a debate over positivism, or specifically, the extent to which models should be realistic. There are certainly positivist/empiricist elements to the debate (i.e., Elster's stipulation that mechanisms are easily observable), and yet causal mechanisms tend to presuppose a realist view that sharply contrasts with strict positivism. Rather than entailing some fundamental disagreement over positivism, debates over observability may be reconcilable to the extent that observablists accept that mechanisms are not reducible to empirical variables and unobservablists accept that mechanisms entail empirical consequences that, at least theoretically, could be identified.

A Conceptual Core?

These differences do not necessarily threaten a coherent mechanisms account. Rather, they may indicate different

subtypes of a concept on which there is a basic consensus. In fact, despite their differences, the accounts we have considered largely agree on the following points: Firstly, mechanisms provide an important alternative to covering laws; secondly, mechanisms provide justification for a realistic approach to the social world; and thirdly, mechanisms provide an intuitive description of causal relationships that focus on processes.

In defining this consensus, Gerring (2007) proposes that various approaches to mechanisms rest upon the core concept of a mechanism as 'the pathway or process by which an effect is produced or a purpose is accomplished' (178). Gerring notes that elaborations on this core are peripheral, properly regarded as 'arguments about mechanisms rather than the definition of mechanism' (178). When mechanisms are defined simply as chains of causation, many debates over mechanisms can constructively be reconceived as debates over mechanism subtypes.

However, while mechanisms can productively be thought of as simple causal pathways, there is a worry that this definition masks two fundamentally different views – it is questionable whether theorists would agree that just any process is a causal mechanism.

The first of these views about mechanisms is based on an understanding of explanation that depends upon generalization or unification. Mechanisms are said to be explanatory insofar as they organize knowledge, either into middle-range theories (Merton, 1968) or universal processes (Elster, 1998) that are widely instantiated. These views thus draw on a top-down approach to explanation, whereby we explain an event by showing that it is an instance of a general pattern. On this view, explanation by causal mechanisms requires that mechanisms are robust processes. Philip Kitcher (1989) presents the unificationist view:

> The heart of the unification approach is that we cannot make sense of the notion of a basic mechanism apart from a systemization of the world in which as many consequences as possible are traced to the prediction of as small a number of basic mechanisms as possible.

While many mechanistic approaches in the social sciences are less specific about the requirement of unification, a commitment to generalization remains. A single historical process, for example, would not count as a causal mechanism with any sort of explanatory value.

The second view about mechanisms is fundamentally different. It corresponds to a 'bottom-up' approach in which explanation is said to consist in identifying the chains of causal relations, complete with details of their context, which link a cause and an effect. Glennan (2002) refers to this as 'actual sequence explanation,' in which explanation consists in listing the contextual or historical particulars of a causal chain. Empirical researchers who orient themselves against black-box statistics typically espouse this view: whereas black-box approaches view causality as a relation at a distance of counterfactual dependence, mechanisms, on the other hand, view causality as a productive process where the links between cause and effect are identified. This 'bottom-up' view of mechanisms is consistent with theories that define mechanisms as causal chains, without the requirement that they refer to generalizable processes (Woodward, 2002; Bunge, 2004).

The epistemic goals of the 'bottom-up' or 'actual-sequence' view are often distinct from that of the 'top-down' view. For the 'bottom-up' view, part of the epistemic value of mechanisms consists in identifying information that is helpful (at least theoretically) for intervention or prediction. For example, one might want to know the mechanism that links a specific job training program to employment outcomes in order to predict the program's effect in new contexts, or to identify whether there are other efficacious ways to bring about the desired outcome. By 'opening the black-box,' mechanisms provide causal information that is better equipped than average causal effects in identifying the social levers that allow for change (Reskin, 2005; Morgan and Winship, 2007). In sum, 'bottom-up' explains by providing detail, while 'top-down' explains by achieving abstraction.

These two approaches are not necessarily mutually exclusive: after all, digging into a causal relationship may identify a mechanism that is an instance of a generalizable causal pattern. Despite this, it seems that the kind of explanation that undergirds each approach is distinct. That is, the different emphasis on disaggregation as opposed to aggregation may indicate that there is no conceptual core that can intelligibly serve as a foundation for both approaches. It is out of the scope of this article to provide a definitive answer; yet I hope that identifying this possible crux serves as a small step toward clarification.

Conclusion

This article has discussed five major approaches to causal mechanisms. I have argued that many seemingly divergent views rest upon a core conceptual consensus, one that orients social-scientific explanation away from constant conjunction and toward process identification. At the same time, the literature on mechanisms does contain points of deep contention. This article has raised the question of whether there are two distinct approaches to causal mechanisms, each with its own explanatory agenda. While it was not in the space of this article to fully investigate this question, identifying potential points of consensus and conflict is an important and necessary step toward conceptual clarity.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright
Orlando, Florida
January 2015

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

This article is a revision of the previous edition article by J. Groebel, volume 14, pp. 9458–9463, © 2001, Elsevier Ltd.

Abstract

Decades of research have shown that the relationship between media and childhood is not unidirectional but reciprocal. In this article, both directions of the media–child development relationship are presented. We discuss how child development predisposes children's media use and preferences by reviewing key developmental characteristics of four periods across childhood, the typical media use during each period, and then hypothesizing how these characteristics influence media use and preferences. Next, we present an overview on the negative and positive influences of media that are most prominent in the public debate. We conclude by identifying directions for future research.

Children's media has become a global, multibillion dollar business. From the beginnings of life, children in the twenty-first century are developing in front of a screen (Wartella and Robb, 2011). Infants now have a wide array of DVDs available for them. The early childhood television market has fierce competition as marketers try to reach this financially profitable audience through programming, advertisements, and licensing deals. Children in middle childhood are now playing video games at rates higher than ever before, while 80% of adolescents are now using social network sites such as Facebook to connect with peers (Lenhart et al., 2011). Media entertainment has become so pervasive in children's domestic and school environments that cultural commenters have alluded to this as the 'entertainization' of childhood (Gabler, 1998).

Given the proliferation of entertainment media, it is important for researchers, health practitioners, and public policy advocates to clearly understand the current media landscape of children. This includes understanding the intricate relationship between media and child development. Decades of research into children and the media have shown that the relationship between media and childhood is not unidirectional but reciprocal. In this article, we address both directions of the media–child development relationship. In the first part, we discuss how child development predisposes children's media use and preferences. In the second part, we discuss how media use influences child development. We conclude by identifying gaps in the literature that are critical for future research.

How Development Influences Children's Media Use and Preferences

The media children use, and in particular their media preferences, are predicted – in a large part – by their developmental capabilities. Researchers have suggested that young children have a preference for media that can at least be partly incorporated into their existing framework and that they show less preference for extremely simple or extremely complex stimuli (e.g., Anderson and Lorch, 1983). This moderate-discrepancy hypothesis predicts that at any given age, a moderate level of stimulus complexity is preferred and that this level increases as the child matures (Valkenburg and Cantor, 2000). First incorporated into Helson's adaptation level theory on sensory habituation (Helson, 1948), the moderate-discrepancy hypothesis has proven to be a plausible explanation for behavioral and sensory regulation (e.g., Berlyne's general theory of curiosity, Berlyne, 1960) as well as a viable explanation for why the media preferences of children in various age groups differ so greatly. After all, the perceived simplicity and complexity of media content changes dramatically as children mature. Media content that is only moderately discrepant and therefore attractive to 2-year-olds may be overly simple and thus unattractive to 6-year-olds.

As such, in order to understand children's media usage and preferences, it is important to understand how children typically develop. To that end, we present a brief review of key developmental characteristics of four periods across childhood (i.e., infancy and toddlerhood, early childhood, middle childhood, and adolescence) and hypothesize how these characteristics influence children's media use and preferences. We also present statistics regarding the amount of media that is typically consumed during each period. In this article, we mainly present data from American media use studies. However, the media use patterns presented here are similar to other industrialized countries as well (Beentjes et al., 2001; Szybist, 2011).

Infants and Toddlers

This age group involves children between birth and 2 years. In the first 2 years of life, children exhibit significant growth as they move from relying on basic reflexes to engaging in more purposeful behaviors around 18 months of age (Bukatko, 2007). When children are around 4 months of age, they begin to exhibit some interest in television watching. This onset is not accidental. At 4 months of age, the social smile emerges: infants start to laugh when they see or hear things they like. At the same time, their ability to detect cues in their environment has matured as has their ability to locate a sound in space by turning their head or eyes in the direction of the sound (Field et al., 1980).

In the first year of life, the orienting reflex mainly predetermines attention. Infants are typically interested in sudden

and novel sounds and movements along with bright colors. In the second year, attention becomes somewhat less influenced by novelty and more influenced by relevant and interesting content. By 18 months of age, their first problem-solving skills (means-end behavior) emerge, and with this, a preference for solving simple puzzles and playing simple games also emerges. Infants and toddlers have limited language skills, although they begin to experience a word spurt of nearly 20 new words per week around 18 months of age (Bukatko, 2007). At this point, they enjoy verbally labeling familiar objects (boat, house, train) and creatures (dog, cat) that they recognize when presented with a storybook or audiovisual media.

Media use for this age group is a rather controversial topic. Beginning with the introduction of *Baby Einstein* in the late 1990s, media for the infant and toddler demographic have become an enormous international industry (Christakis, 2009). And yet, many health care practitioners argue that we do not yet know enough about the (potentially negative) influence of media on this audience (e.g., Christakis, 2009). These and other similar concerns have brought about an emergence of public policy initiatives. For example, in the United States, the American Academy of Pediatrics discourages screen media exposure in the first 2 years of life (Council on Communications and Media, 2011), while France has taken the step of banning programming directed at infants. Yet, despite these efforts, recent data show that the average child under 1 year of age is exposed to nearly 1 h of television daily, and by 2 years of age, these rates are closer to 2 h of daily exposure. To put this in a historical context, in 1971, the average age at which children began watching television was about 4 years old. As discussed, today it is 4 months (Christakis, 2009).

Despite the relatively contentious debate on whether or not media is appropriate for this young audience, we do know that infants and toddlers exhibit very distinct media preferences. For example, this young audience prefers content that relies heavily on music and song. We also know that content with salient formal features is best able to hold children's attention. This preference wanes slightly as children become older toddlers (around 18 months old) and is replaced by an interest in simple narratives. Given their limited cognitive and verbal skills, content that relies on slow pacing, familiar contexts, incorporates significant repetition, provides opportunities for verbal labeling, and incorporates simple characters is also appealing for this group.

Early Childhood

Early childhood covers children between 3 and 6 years old. During this period of time, children typically demonstrate egocentrism (i.e., an inability to separate their own perspective from the perspectives of others) as well as perceptual boundedness (i.e., tendency to focus on immediately perceptible attributes of an object, whereas other types of information are ignored) and centration (i.e., tendency to focus on an individual, striking feature of an object, to exclude other less striking information) (Bukatko, 2007). Early childhood is characterized by an inability to distinguish between fantasy and reality. Although as of 18 months, most children are able to distinguish fantasy from reality in their own imaginary play, they are less able to do so when they need to judge the reality status of objects and stimuli in their environment, including the media.

Early childhood is also characterized by rapid emotional developments (Thomas, 2005). Newborns can produce facial expressions associated with primary emotions such as joy, sadness, and anger. However, at the onset of early childhood, children start to experience so-called conscious emotions, such as envy, guilt, and embarrassment. Conscious emotions differ from primary emotions in that they require perspective-taking skills (e.g., the notion that someone is disappointed with you). By age 4 years, children are able to understand these more complex conscious emotions in others. However, their detection of emotions is still perceptually bounded. Children in this age group are only able to recognize emotions based on external cues (e.g., crying; sad face) and not based on less perceptual cues.

Today's early childhood media market is one of the most competitive and crowded markets across the media landscape. Media use reports indicate that children between 3 and 6 years old spend nearly 3 h per day using media (Common Sense Media, 2011). Younger children (3 years) spend the majority of their media time using television. As children get older (4–6 years), we see that they also begin to add video games to their daily media diet (approximately 30 min per day). Unsurprisingly, nearly no time is spent engaging in social media use or other forms of interactive media use (e.g., Internet use, text messaging) during early childhood.

During early childhood, attention to media content increases dramatically (Valkenburg and Vroone, 2004). This reflects the rapid increase in children's information processing skills and their improved vocabulary. However, their cognitive and emotional capacity is still limited. Children in early childhood lack experience and semantic knowledge (e.g., grass is green; a chair has four legs), which can make processing new media content quite challenging. As a result, they typically prefer media content that relies on slow pacing, incorporates repetition, and contains simple characters in familiar contexts. These preferences may change at the end of early childhood when children, especially boys, become more attracted to fast-paced media, more complicated characters, and adventurous contexts.

The perceptual boundedness that is characteristic of early childhood also induces children to judge media characters on perceptually salient features, such as their appearance and perceptually visible motives and emotions. And, because of their inability to distinguish fantasy from reality in media, fantasy characters are just as attractive and engaging as real-life characters. By the time they are 3 years old, children start to make statements indicating attachment to television personalities. But they can be just as much or even more attracted to animals or cartoon characters than to real-life characters. Children in this age group are also very impressed by 'special effects' such as a character vanishing into a puff of smoke.

Middle Childhood

Middle childhood involves children between 7 and 11 years old. The most important difference between early and middle

childhood is that children in middle childhood begin formal schooling. During this stage, thought processes become more mature and adultlike. Although children are still unable to engage in abstract and hypothetical thinking, they are now able to think logically and solve problems in a logical fashion so long as the problems apply to concrete events or objects. Children can now clearly distinguish between fantasy and reality, and as a result, their admiration for cartoon characters decreases dramatically. Emotional development continues to improve in sophistication. Children are now better able to understand their own emotions and the emotions of others. Relatedly, children are increasingly able to understand the perspective of others. The combination of formal school entry and understanding other's perspectives results in an important focus on peer relationships.

Children in middle childhood continue to incorporate media into their daily lives at relatively high rates. In the beginning of middle childhood, we see estimates similar to early childhood with approximately 3 h per day spent using media – most of which is predominantly television (about 40 min with games, Common Sense Media, 2011). However, around age 8 years, children spend nearly 4 h per day viewing television, 1 h per day playing video games, and 30 min per day using social media sites (Rideout et al., 2010). Although television viewing is certainly increasing throughout middle childhood, these estimates highlight an increased interest and use of interactive media.

Along with an increased interest in interactive media, there are several other changes in middle childhood that influence media preferences. Beginning at age 6 years, children lose their interest for slow-paced educational programs such as *Sesame Street* and develop a preference for entertainment media that is faster and more complex. They also begin to develop an interest for action and violence. For this reason, there is an abundance of media entertainment developed for this age group that contains action, violence, and binary characters (i.e., good/bad, male/female). During middle childhood, children begin to 'decentrate' and develop an interest in detail. As a result, they prefer more complicated media characters and more sophisticated plotlines. That said, given that they still struggle with abstract thinking, they prefer content that focuses on concrete problems and objects (e.g., the quest for a treasure; saving a princess). Although children now understand the difference between fantasy and reality, not all children are equally interested in realistic content at this age. Girls typically develop an interest in real-life entertainment, whereas many boys continue to be attracted to fantasy content (e.g., *Transformers*, *Power Rangers*). There is also a change in character preference. While early childhood was characterized by a focus on character appearance, the increased emotional development of middle childhood results in a greater focus on the psychological characteristics of media characters. Children now enjoy characters with which they can psychologically identify, for example, characters with an attractive sense of humor.

Adolescence

Adolescence, which covers the period between 12 and 18 years old, is accompanied by rapid physical, psychological, and cognitive changes (Bukatko, 2007). Physical changes include both rising hormone levels (McClintock and Herdt, 1996) as well as brain development (Blakemore and Choudhury, 2006). In particular, the prefrontal cortex – an area of the brain responsible for decision making, planning, inhibiting inappropriate behavior, and understanding social relations – is developing dramatically. These physical changes also lead to psychological changes. For example, adolescence is often characterized by mood swings, more risk-taking behavior, and increasing sexual interest. Alongside these physical and psychological changes, cognitive development improves greatly and reaches an adult level at age 15 years. Adolescents are able to think abstractly and in a more sophisticated manner, and now possess the capacity for higher order reasoning.

Egocentrism reemerges during this period as adolescents become self-absorbed (i.e., viewing things from only their point of view) and idealistic (Thomas, 2005). This makes adolescents highly critical of authority figures (e.g., parents and teachers). Also as a result of this egocentrism, an imaginary audience may develop, that is, the belief by adolescents that others are constantly watching and thinking about them. Peer relationships are quite important to adolescents, and as they begin to establish their own unique identity, the imaginary audience perspective results in them looking to their peers for advice and support. Lastly, this egocentrism often leads adolescents to feel as though their own experiences are unique, which sometimes can result in risk-taking behaviors.

Media represent an important component of adolescents' daily life. Adolescents are spending more than 8 h per day using some form of media (Rideout et al., 2010). While television reigns supreme in terms of time (i.e., nearly 5 h), adolescents are spending nearly 3 h per day playing video games and using the Internet (e.g., social network sites, instant messaging, Rideout et al., 2010). Given the increased importance of peers during this period, it makes sense that adolescents would turn to the Internet – particularly social media – to foster and maintain these connections.

The physical, psychological, and cognitive changes that occur during adolescence strongly influence media preferences. First, because of the ability to think in an abstract manner, adolescents prefer more complex media compared to children in middle childhood. In particular, they prefer media that is developed for an adult audience. Horror movies, programs with an element of fear (e.g., *Jackass*), risk taking, sarcasm, and other forms of crude humor are specifically appealing to this audience. Second, perhaps as a result of their increased idealistic views, adolescents also prefer media with social lessons (e.g., solutions to social problems) and enjoy watching older characters that they can admire. Lastly, adolescents are particularly interested in using media that enable them to connect with friends as well as exercise self-expression and identify formation (e.g., social network sites such as Facebook, content creation sites such as YouTube, Greenhow et al., 2009).

The Effects of Media on Child Development

Given the developmental limitations of young audiences, the amount of time that children spend using media, and the constant evolution of media, it is unsurprising that many researchers are concerned about the potential influence of

media. In fact, these concerns have fueled more than 50 years of research on the role that media play in children's lives (e.g., Pecora et al., 2007). Beginning in the 1950s, much of this research focused on the negative effects of media on child development – with particular attention to the role of media violence on aggression. By the 1970s, with the emergence of *Sesame Street*, researchers also began to ask whether media could positively affect children's development. Although a complete review on the positive and negative influences of media is beyond the scope of this article, we present an overview of the effects of media that are most prominent in the public debate. We begin with outlining several negative outcomes associated with media use including aggressive behavior, attention-deficit hyperactivity disorder (ADHD)-related behaviors, sexual socialization, sexual risk behavior, materialism, parent–child conflict, and childhood overweight. We then present several positive outcomes associated with media use including prosocial behavior, school readiness, core subject knowledge, creativity, and imagination.

Negative Effects

Aggressive Behavior

When it comes to the effects of media on children, the influence of violent media on aggressive behavior has received the most research attention. Hundreds of correlational, experimental, and longitudinal studies have evaluated whether and how violent media exposure is related to subsequent aggression. These studies have typically looked at the influence of violent media exposure in middle childhood and adolescence (e.g., Gentile et al., 2004; Huesmann et al., 2003), although some studies have also investigated violent media effects in early childhood (e.g., Christakis and Zimmerman, 2007). The majority of studies have evaluated the influence of violent television content (e.g., Bushman and Huesmann, 2001) on aggression, although in recent years the influence of violent interactive media (e.g., video games and computer games) has received increased research attention (e.g., Anderson and Dill, 2000).

While some studies have suggested no relationship between violent media exposure and aggression (e.g., Ferguson et al., 2011), most demonstrate that watching violent television or playing violent video games is positively related to aggressive behavior and may even lead to aggressive behavior later in life (e.g., Huesmann et al., 2003). Meta-analytic research supports this argument. Paik and Comstock (1994) conducted a meta-analysis to ascertain the effect size associated with violent movies and violent television programs, whereas Anderson and Bushman (2001) were interested in the effect size associated with violent video games. Both analyses suggested small to moderate effects (i.e., $r = 0.31$ and 0.19, respectively) of violent media on aggressive behavior. Moderator analyses also indicate that the effects of media violence are stronger for boys than for girls and stronger for younger than for older children (Paik and Comstock, 1994).

Several theories have been used to explain how violent media content can increase aggressive behavior. Two of the most widely used theories are social cognitive theory (Bandura, 2001) and desensitization theory. According to social cognitive theory, children learn behavior not only through their own experiences but also by observing others. When children see others behave in a certain way and subsequently being punished or rewarded for this behavior, children learn which behaviors are socially acceptable and which ones are not. These social cognitions then help guide the actual behavior of children. Desensitization theory, on the other hand, states that repeated exposure to media violence leads to a gradual habituation in response to displays of aggression. Over time and with increased exposure to media violence, children become more accustomed to aggressive behavior, which subsequently impacts moral judgments and behaviors.

In light of the large body of research on violent media exposure and aggression, most media researchers today accept that violent media exposure plays a role in children's aggressive tendencies. Many of these researchers also argue that both social cognitive theory or desensitization theory are fair explanations for this relationship. Yet, these same researchers acknowledge that there remain many unanswered questions. For example, we know little about which children are most susceptible to violent media exposure and also how family or peer environments may moderate this relationship. Research that seeks to identify who is most susceptible to the influence of violent media is a critical area for future research.

ADHD-Related Behaviors

ADHD is a behavioral disorder characterized by elevated levels of inattentiveness, hyperactivity, and impulsivity (American Psychiatric Association [DSM-IV-TR], 2000). Although ADHD is a clinical diagnosis, many authors considered ADHD as the extreme end on a continuum of behaviors. In recent decades, there has been an increase in the number of children diagnosed with ADHD (e.g., Akinbami et al., 2011) and receiving pharmacological treatment for ADHD-related behaviors (e.g., Hollingworth et al., 2011).

There have been recurrent claims that specific features of entertainment media may cause children's ADHD-related behaviors (Christakis, 2009; Nigg, 2009). Most of the claims focus upon children in early and middle childhood, as these are the periods in which ADHD diagnoses typically occur. While the research investigating these claims remains limited, existing research supports the argument that time spent with media (television and video games) may play a role in subsequent ADHD and ADHD-related behavior (Christakis and Zimmerman, 2007; Miller et al., 2007). For example, in longitudinal research, Swing et al. (2010) found that television and game exposure was related to greater attention problems in a middle childhood sample. Other researchers have gone beyond global exposure amounts to look at the relationship between specific media content and ADHD-related behaviors. This research has shown that violent media content is related to more attention problems (Kronenberger et al., 2005) and impulsivity (Anderson and Maguire, 1978).

To date, most of the effects of entertainment media use on ADHD-related behaviors have been attributed to the violent content of media. An important hypothesis associated with this is the arousal-habituation hypothesis. This hypothesis posits that violent media negatively affect children's basic arousal level, which may subsequently lead to attention problems, hyperactivity, and impulsivity (Huizinga et al., 2013).

Although the existing literature intimates a positive relationship between (violent) media exposure and ADHD-related

behaviors, research in this field is still in its infancy and there remain many gaps in our understanding of this relationship. For example, most existing work has mainly focused on the direct relationship between media use and ADHD-related behaviors. Future research should investigate underlying mechanisms and test whether and if the arousal-habituation hypothesis sufficiently explains this relationship. More research on the effect of fast-paced media on ADHD-related behaviors is also needed in order to differentiate between the effect of fast-paced media and violent media. Finally, evaluating the role of individual differences is an important direction for future work.

Sexual Socialization and Sexual Risk Behavior

Sexual socialization – that is, the process by which knowledge, attitudes, and values about sexuality are acquired (Ward, 2003), typically begins during adolescence. The media are consistently acknowledged as an important agent of adolescents' sexual socialization (see Ward, 2003 for a review). Adolescents are heavy users of media and the media they consume frequently include sexual content. As a result, they are exposed to an abundance of sexual content in television, movies, magazines, and the Internet – and this content has caused many researchers to ask what the effects of such exposure might be.

To better understand how sexual content is presented in the media, researchers have conducted content analyses of frequently used media such as television and the Internet. A content analysis from the United States, for example, indicated that two out of three programs on television (aside from sports, news and children's programs) contain some sexual content, whereas only 1% of these programs place primary emphasis on sexual risks or responsibilities (Kunkel et al., 2007). Furthermore, sexually explicit material (SEM) is easily accessed on the Internet. In online SEM, sex is often portrayed as a merely physical, self-indulgent activity between uncommitted partners with few negative consequences (e.g., Mehta, 2001). This portrayal of sex in the media is thought to increase sexual risk behavior in adolescents. Empirical research has in fact found that exposure to sexual media content can result in earlier initiation of sexual behavior (e.g., Brown et al., 2006; Collins et al., 2004), increased sexual risk behavior such as unprotected sex (Peter and Valkenburg, 2011), and objectification of women (Peter and Valkenburg, 2007).

The negative effects of sexual media content on adolescents' sexual behavior are typically explained by cultivation theory (Gerbner et al., 2002). Cultivation theory states that heavy media users, when compared to light media users, are more likely to believe that the real world is similar to the messages portrayed in the media. Therefore, if casual sex is often portrayed as not having any negative consequences in the media, heavy media users are more likely to believe this message.

The research to date certainly supports researchers' efforts to understand how sexual media content is related to adolescents' sexual behavior. However, most of the research has been conducted within relatively homogenous populations (e.g., American youth, Dutch youth). Considering that attitudes toward sex and sexual behaviors are dependent on culture and religiosity (Marston and King, 2006), efforts to compare media effects across different countries would be worthwhile. Furthermore, efforts to identify explanatory factors, such as perceived vulnerability or perceived norms of sexual behaviors, would provide important information to researchers interested in understanding the process of how sexual media affect adolescents as well as ways to circumvent this process.

Materialism, Parent–Child Conflict, and Childhood Overweight

As the children's media environment has become increasingly commercialized, advertising has become an important aspect of children's media exposure. More than ever, advertisers now view children as an important and relevant target group. And advertisers now rely on a host of technologies to reach these young audiences – ranging from traditional television commercials to branded Web sites and brand placement in video games. Along with this consistent growth in child-directed advertising, we have seen an increase in concerns associated with the negative influence of advertising on children's behavior and well-being. These concerns have predominantly focused on the negative influence of child-directed advertising on materialism, parent–child conflict, and childhood overweight. Research investigating these outcomes has typically looked at the effects of television advertising (e.g., Halford et al., 2004), although research has begun to address newer advertising formats found in video games and the Internet (e.g., Henry and Story, 2009).

In terms of materialism, scholars have argued that the inherent nature of advertising (i.e., it is designed to arouse desires for products that would otherwise not be salient) makes children more materialistic. Cross-sectional, experimental, and longitudinal studies have indeed demonstrated that advertising leads to an increase in materialism in children (Buijzen and Valkenburg, 2003; Greenberg and Brand, 1993; Opree et al., 2013). Furthermore, researchers have also argued that the exposure to advertisements leads to increased parent–child conflict because children will ask for the advertised products and parents do not want to comply. Indeed, studies have shown that advertising increases product requests and these product requests subsequently induce parent–child conflict (Buijzen and Valkenburg, 2003).

Finally, in recent years, advertising has been implicated as an important factor in children's likelihood to become overweight or obese. Researchers argue that the preponderance of junk food advertisements has created a generation of children who expect a heavy presence of these foods in their diets, and parents who opt against this practice are thought to act outside the norm (Jordan, 2007). As a result, advertising exposure is said to stimulate intake of high-calorie and low-nutrient food and beverages among children, which subsequently leads to overweight and obesity (food advertising effects hypothesis, Gantz et al., 2007). A growing body of empirical research supports this contention (e.g., Borzekowski and Robinson, 2001; see also Buijzen and Valkenburg, 2012).

The evidence for the negative influence of advertising on children is rather convincing. While more studies are needed to identify those children who are most susceptible to the negative effects of advertising, it is also important to recognize that advertising is part of today's consumer culture. Although one can imagine taking steps to limit children's exposure to violent media content or sexual media content, it is harder to imagine ways to limit children's exposure to advertising content. Perhaps as a result of this fact, scholars are now investigating

ways to help children become more resistant to advertising messages (e.g., by teaching advertising literacy) as well as identifying whether and how the power of advertising can be used to promote healthier outcomes in childhood (e.g., healthier eating).

Positive Effects

All too often, discussions surrounding the effects of media in childhood focus upon negative effects. And while accurate and certainly of concern, these negative effects do not present the entire picture. Far less attention has been paid to the role of developmentally appropriate media in supporting positive outcomes among children. Yet, as Fisch (2004) has observed, if we believe that children can learn negative lessons from media, it stands to reason that they can learn positive lessons too. To that end, we review the existing research on the positive impacts of media on prosocial behavior, school readiness skills, core subject knowledge, creativity, and imagination.

Prosocial Behavior

Prosocial behavior refers to a range of positive behaviors including positive interactions (e.g., friendly play or peaceful conflict resolutions), altruism (e.g., sharing, offering help), and behaviors that reduce stereotypes (Mares and Woodard, 2007). Researchers who believe that media can influence prosocial behavior argue that depictions of prosocial behavior in the media are more consistent with social norms than antisocial behavior, and as a result, imitations of these behaviors are more likely to be received positively than imitation of antisocial acts (Rushton, 1979).

Since the late 1970s, more than 30 studies have been conducted to identify whether and how prosocial media content might contribute to prosocial behavior. These studies have largely focused upon the relationship between prosocial television content and subsequent prosocial behavior (e.g., *Mister Rogers' Neighborhood*, Friedrich and Aletha Huston, 1973). A meta-analysis by Mares and Woodard (2007) revealed that children who watched more prosocial television content exhibited significantly more prosocial behavior. The overall effect size ($r = 0.27$) resulting from this meta-analysis is similar to that found in meta-analyses of the relationship between violent television content and subsequent aggression. Television is therefore just as prone to fostering prosocial behavior as it is to fostering aggression (Mares and Woodard, 2007). The relationship reported by Mares and Woodward was strongest when prosocial behaviors were explicitly modeled in the television show. Moreover, children's age moderated this relationship such that the effect of prosocial content increased sharply during early childhood, peaked at age 7 years, and then declined until and throughout the teen years. Mares and Woodard (2007) posit that the peak in middle childhood suggests that younger children may lack the cognitive ability to fully understand prosocial acts on television. More research is needed to understand why the relationship weakens after middle childhood. A possible explanation is that this decrease in effect is due to a dearth of developmentally appropriate prosocial television content available for older children.

Recent studies also suggest that interactive media that are designed to support prosocial behavior do work. In a series of studies conducted in three countries across three different age groups (i.e., middle childhood, adolescence, adults), researchers found robust evidence to support the argument that playing video games in which characters model prosocial behavior does increase short- and long-term prosocial behaviors (Gentile et al., 2009). Similar findings have been found by other scholars investigating the relationship between prosocial video game play and subsequent prosocial behavior, particularly in middle childhood and adolescence (Saleem et al., 2012).

Overall, the literature indicates that exposure to media that explicitly depict prosocial behavior does subsequently result in children enacting this behavior. This effect is most typically explained through Bandura's social cognitive theory (Bandura, 2001) or via the general learning model (GLM) (Gentile et al., 2009). Both models focus on the imitation of modeled behaviors, although the GLM pays particular attention to affective, arousal, and cognitive effects during media use. These theories have helped researchers identify why prosocial media content can be beneficial for children, yet there remain many unanswered questions. In particular, more research is needed to identify best practices when creating prosocial media content for children. We also know little about the role of individual differences in determining who is exposed to prosocial content and how individual differences impact processing of this content.

School Readiness

School readiness refers to children's abilities to engage in and benefit from formal schooling. This concept encompasses early academic skills as well as social and emotional development. The majority of research on media and school readiness has focused on the role of television in early childhood. More than 1000 studies, for example, have examined the influence of the television program *Sesame Street* on children's school readiness. The earliest of these studies (Ball and Bogatz, 1973; Ball et al., 1974) was a pair of experiments testing the effectiveness of the first two seasons of the program. Results indicated that *Sesame Street* viewers showed significant gains across a host of school readiness skills. These effects have been replicated and extended in numerous correlational, experimental, and longitudinal studies since then – both with the American version of *Sesame Street* as well as international coproductions of the program (Fisch, 2004). In fact, a recent meta-analysis on the effects of the international coproductions of *Sesame Street* revealed significant positive effects of exposure to the program on children's school readiness skills (Mares and Pan, 2013). *Sesame Street*, however, is only one example of a program that has been shown to support school readiness. There are many others including *Barney & Friends* (Singer and Singer, 1994), *Blue's Clues* (Anderson et al., 2000), and *Pinky Dinky Doo* (Linebarger and Piotrowski, 2009). What these shows, and others like them, have in common is that they were developed with the explicit intent to support school readiness skills. Building upon formative and summative research, these programs merge best pedagogical practices with an understanding of the needs and preferences of young audiences.

Compared to television, evidence to support the benefits of interactive media on school readiness remains in its infancy. The available research indicates that developmentally

appropriate interactive media designed with the explicit intent to support school readiness skills are effective (see Lieberman et al., 2009). However, more work is needed to understand how the benefits of interactivity can be capitalized upon to support school readiness skills.

The mechanisms to explain how media affect school readiness skills are less frequently discussed in the literature. Some researchers proscribe to the capacity model (Fisch, 2004) – a model of children's learning from television (and, to some extent, interactive media) that focuses upon children's allocation of working memory to media content, while others focus on modeling-based theories such as social cognitive theory (Bandura, 2001). The notable theoretical consistency across studies investigating school readiness is the recognition that young children are active viewers who use the formal features embedded within media to guide their attention and comprehension (Anderson and Lorch, 1983). However, much more research is needed to understand the theoretical mechanisms to explain when, and for whom, media can support school readiness.

Core Subject Knowledge

Core subject knowledge refers to a broad array of information and skills that children are introduced to during formal schooling including literacy, mathematics, and science. The majority of research looking at the relationships between media use and core subject knowledge has focused on the role of television in middle childhood. For example, experimental research with the literacy-based program *Between the Lions* found that daily exposure to the program, over the course of 4 weeks, resulted in significant literacy gains (Linebarger et al., 2004). Similarly, experimental research with the math-focused television show *Cyberchase* revealed positive results on children's mathematical problem-solving skills (Fisch, 2003). And research looking at the influence of television on science skills has shown that television programs designed to support science knowledge (e.g., *The Magic School Bus* and *Bill Nye the Science Guy*) do support viewers understanding of scientific concepts as well as how to engage in the process of scientific discovery (ARC Consulting LLC, 1995; Rockman et al., 1996). Like school readiness, these and other similar findings illustrate that developmentally appropriate media content designed with the explicit intent to support children's core subject knowledge is effective.

The available research on interactive media also suggests that interactive media can support core knowledge. For example, children who actively use the Web site corollary of the program *Cyberchase* demonstrated gains in their mathematical problem-solving skills – particularly when used in combination with the television program (Fisch et al., 2010). Similarly, electronic storybooks can support children's reading comprehension (Doty et al., 2001) and phonics skills (McKenna et al., 2003) and using interactive media to demonstrate scientific concepts results in better concept comprehension when compared to standard lessons (Ardac and Akaygun, 2004).

Despite the growing knowledge base on the role of media in supporting children's core subject knowledge, the mechanisms to explain how media support these skills are less known. As with school readiness, the capacity model (Fisch, 2004) and social cognitive theory (Bandura, 2001) emerge as the two most prevalent explanations for these effects. However, the paucity of theoretical research on why and how media can affect core knowledge skills highlights a critical area for future research.

Creativity and Imagination

Creativity and imagination are multifaceted concepts that are operationalized in different ways throughout the literature. Creativity is most typically defined as the ability to generate many different novel or unusual ideas (Valkenburg and van der Voort, 1994), and is commonly evaluated during middle childhood and adolescence. Imagination is typically divided into two subcategories: (1) imaginative play, which is defined as play in which children transcend reality by acting 'as if,' and (2) daydreaming, which is defined as a state of consciousness in which attention turns to thoughts or images that are based on memory (Valkenburg and Calvert, 2012). Imaginative play typically occurs during early childhood years while daydreaming is more likely to occur in middle childhood and throughout adolescence.

Surprisingly, little research has been done to evaluate whether media can support creativity and imagination during childhood. In the early 1990s, Valkenburg and van der Voort conducted a pair of reviews to identify whether television supports or hinders children's creativity and imagination (Valkenburg and van der Voort, 1994; van der Voort and Valkenburg, 1994). The results of these reviews suggested that television viewing in general hinders children's imaginative play and creativity. However, television programs that are designed to stimulate creativity and imagination may actually do so (see Valkenburg and Calvert, 2012). For example, research with the television program *Barney* (a program designed specifically to stimulate children's imagination) indicated that, after 2 weeks of viewing the program, viewers demonstrated more imaginative play than their nonviewing peers (Singer and Singer, 1998). Longitudinal evidence also revealed that viewing educational television during early childhood was associated with increased creativity during adolescence (Anderson et al., 2001).

Just as research on television is limited, research on the role of interactive media in creativity and imagination is equally scarce. Given the contingent feedback that is characteristic of interactive media, and given that such feedback has been shown to support innovation, scholars have wondered why interactive media have not taken a more prominent role in training children to be creative (Fishman, 2004; see also Singer and Singer, 2011). Moreover, in an era where children can design avatars and various trial selves to interact in cyberspace, where they can create their own videos (e.g., YouTube) and share them with others, where they can play games that allow them to construct their own homes, cities, landscapes (e.g., Sim), the potential benefits of interactive media on creativity and imagination seem vast. And yet, presently, we know very little. Correlational evidence suggests that video game playing can support creativity in middle childhood and adolescence (see also Calvert and Valkenburg, 2013; Jackson et al., 2012), but causal evidence to support this finding does not yet exist. Future efforts to understand whether and how interactive media can support children's creativity and imagination are warranted.

Conclusion

Media use and child development are reciprocally linked processes. This article has demonstrated this reciprocal relationship by illustrating how development plays a predictive role in children's media use and preferences as well as how media use subsequently impacts development in both positive and negative ways. Our article on the influence of child development on media usage and preferences highlights the consistent presence of television in children's lives across developmental stages, while at the same time showing that content preferences change dramatically as children get older. Children's preference for interactive media also increases with age. While the very youngest children are not yet engaging with interactive media, children in early and middle childhood are incorporating video games into their daily life, and by adolescence, social media use is daily norm. As technology continues to evolve, interactive media are likely to make inroads into children's lives at younger and younger ages. It will be important for researchers to track these changes in use and preference as well as identify how these changes affect children's lives.

This article also highlights how media can affect child development, making the clear point that quality is much more important than quantity. While it is certainly true that a healthy media diet is one that limits the amount of media children are exposed to, it is also critical to realize that a healthy media diet must pay attention to what children are consuming. Violent content, sexual content, and advertising content are reasons for parental concern and public policy initiatives. Yet on the contrary, developmentally appropriate media content designed with the explicit intent to support healthy outcomes in children can be beneficial for children's cognitive, emotional, and social developments. Efforts to help families achieve a healthy media diet that balances both quantity and quality are worthwhile.

Our article further identifies three important gaps in the literature. First, if one of our goals is to understand how media affect children, then our methods should reflect this. While laboratory experiments will certainly continue to provide important information regarding causality, longitudinal research designs are needed to help researchers assess the long-term consequences of children's media use without sacrificing external validity.

Second, all too often, the potential underlying mechanisms to explain why media affect children are ignored. In some cases, this results from the use of theories that do not carefully explicate the role of specific mediating and moderating variables (e.g., social cognitive theory, see Valkenburg and Peter, 2013). In other cases, researchers theorize about underlying mechanisms but do not provide empirical support to substantiate these claims (e.g., arousal-habituation hypothesis, also see discussion in Potter, 2011). As a result, after more than 50 years of research, although we can say with some confidence that violent media exposure is related to subsequent aggression, it remains largely unclear "*which* effects of *which* kind of media violence on *which* types of aggressive behavior can be attributed to cognitive, physiological, or emotional underlying processes" (Valkenburg and Peter, 2013). Efforts to investigate how media affect children, rather than simply investigating whether they affect children, will make important contributions to the literature.

And finally, researchers must pay more attention to conditional media effects. This article shows that media can have positive and negative effects on children, but it is still largely unclear for whom these effects occur. The most important question for future research is to investigate which children are highly susceptible to positive effects, which are highly susceptible to negative effects, and which are highly susceptible to both. Only by comparing the susceptibles to the insusceptibles can we obtain a true understanding of the role of media in child development.

Abstract

Media history considers the historical dimension of communicating information, knowledge, and values to a broad audience. The numerous approaches to media history share an interest in understanding the impact such structures have had on societies around the globe, the particular forms they have taken, and the dynamics of historical change. Each of these areas is the subject of a significant body of theoretical and empirical work, with many intersections and overlaps, taking examples from the various media, their spatial contexts, and development over time.

Introduction

Media history considers the historical dimension of communicating information, knowledge, and values to a broad audience. Although the term 'media' came into use only in the 1920s to denote the structures of such communication, media history takes account of the period at least from the advent of the handpress in the fifteenth century, and some interpretations include the scriptoria, oral traditions, and wall paintings of medieval times, delving occasionally into ancient and prehistory as well. The numerous approaches to media history share an interest in understanding the impact such structures have had on societies around the globe, the particular forms they have taken, and the dynamics of historical change. Each of these areas is the subject of a significant body of theoretical and empirical work, with many intersections and overlaps, taking examples from the various media, their spatial contexts, and development over time.

Major Trends

The terminus post quem for any media history would be the emergence of writing in several distinct civilizations around the globe some five millennia ago. By decoupling speaker and utterance, lifting language out of a determinate time and space, this episode began a shift in human history, still under way, which has to a large degree shaped the world we share. In the Renaissance age of cultural, economic, and demographical renewal, communication was set on a new footing by the application of movable type, first by Johannes Gutenberg in Mainz, Germany (1439). The first actual printed books, largely modeled on the manuscripts they were intended to replace, were not just luxury commodities, though they mostly circulated in the upper social echelons. Fly sheets and pamphlets reached a broader audience, and over the following centuries a wide variety of popular publications vastly increased the range of the written word and the drawn image.

Almost contemporary with the printing press, manuscript newsletters began circulating in multiple copies along the public mail routes between the major cities of Europe of which some of the best known are those eventually collected by the Augsburg-based Fugger family of merchants. Two to six pages in length, usually anonymous, and distinguished only by place name and date, appearing at regular weekly or biweekly intervals, they bore multiple stories regarding the economic, political, cultural, and religious news of the day. The first newspapers, printed in Strasbourg by Johannes Carolus from around 1605, simply provided word-for-word transcriptions of newsletter material. By 1650, there was already a daily newspaper in Leipzig, and by 1702, in London too (*The Daily Courant*). Over the course of the seventeenth century, in many places newspapers became increasingly differentiated from newsletters in the amount of critical comment they published.

The variety magazine, another seventeenth-century invention, increased the scope for regular publication of communications of all sorts. The new genre emerged directly from earlier media for exchanging cultural news, such as book catalogs and handbills, as well as manuscript letters, still valid conduits between scholars and amateurs alike. From these occasional media to the regular weekly or monthly emission, with a promise of indefinite continuation, of volumes concerning every aspect of cultural activity interesting to amateurs and specialists alike, was not a very great step and the first to take it was Denis de Sallo in his Paris *Journal des sçavans*, published from 1665. Soon afterward came the Roman *Giornale dei letterati* directed by the mathematician Michelangelo Ricci and collaborators. More along the lines of a record of academic work were the *Philosophical Transactions* of the Royal Society, published from 1662.

Important cultural movements thrived on a wider distribution of the products of the press while the printing industry profited in turn. In this light, the European Enlightenment could in some sense be said to be a media phenomenon, indeed, according to Robert Darnton (1979), analyzing the publishing career of Charles-Joseph Panckoucke, it was a business. A veritable explosion of journal publishing brought the ideas of the Enlightenment to larger numbers of readers while the printing trades benefited from advertisement of their wares in the pages of the literary press. Among the new genres developed and diffused in this context were the so-called 'moral weeklies,' notably the German-language *Discourse der Mahlern* (1721–23) published by Johann Jakob Bodmer and Johann Jakob Breitinger, and, directed particularly to female readers, *Die vernünftigen Tadlerinnen* of Johann Christoph Gottsched (1725–1727) all partly stemming from the French

Mercure galant (1672–1714) of Jean Donneau de Visé and others, and especially from the *Spectator* (1711–14) of Richard Steele and Joseph Addison. A similar case could be made for Romanticism as a movement, with necessary modifications to the type and volume of the media involved.

Political movements, too, were accelerated and to some degree shaped by the available media, from the English Civil War to the Masaniello Revolt in Naples, from the French Revolution to the Revolutions of 1848, from the various nationalisms to the Russian Revolution, from the Communist Revolution to the Cultural Revolution in China, from the student revolts of the 1960s to the breakup of the Eastern bloc, all of which have become better understood by a media history perspective. The World Trade Organization protests and the Arab Spring stand as demonstrations of how new generations have mastered the mobilizing possibilities of media-enabled discontent.

Across the centuries, the change-inducing potential of the media has inspired various forms of control exercised by church and state, sometimes in tandem, largely aimed at enforcing a social, cultural, religious, and political status quo. On the one hand, controls and prohibitions could be deployed in such a way as to allow distribution of certain notions among elites, whose very exclusiveness was defined in part by such privileged access; on the other hand, prohibitions could create sites of conflict, where the state or a ruling group could direct selected acts of violence against individuals whose inferiority or exclusion was marked by their vulnerability to such treatment. Among the first in early modern times to articulate the innovative potential of a wider circulation of knowledge was Tommaso Garzoni (1588) in his eulogy of the printing press: "This is the art that indicates the fools, that exposes the arrogant, that makes known those who are learned …." John Milton famously advocated press freedom, although the idea was not taken seriously until the Enlightenment, becoming enshrined first in the United States Bill of Rights in March 1789 and a few months later by the French National Assembly in the Declaration of the Rights of Man and Citizen. Meanwhile, such was the quantity and distribution of the products of the printing press that thinkers like Gaetano Filangieri (1780–1785) referred to public opinion as a 'tribunal.' From the outset, media potential and the imperatives of church, state, and powerful pressure groups have more or less run along a collision course, and mutatis mutandis, they still do today.

To media history may also belong various types of popular entertainment, from music performances to prose theater to opera, which in the nineteenth century attracted a mass following. Indeed, live performance has in certain periods been singled out for special forms of censorship because of the supposed mimetic power. New technology would eventually bring all such entertainments into the homes of millions.

Increasing literacy and increasing demand were met in the nineteenth century by the application of steam power to the printing press (fundamental contributions made between 1802 and 1818) and the use of cheap wood pulp for paper (from the 1840s). Already in the first years of the century, Hegel remarked that perusing the daily morning newspaper had become nothing less than a secular ritual joining readers in a simultaneous act, even if the events read about were no longer fresh. Photography, between 1800 and 1839, introduced the diffusion potential of images, eventually realized in cinematography (1873–96). Radio (1887–95) introduced the diffusion potential of telepresence, realized by television (1897–1925).

As the economic potential of media productivity came to be recognized, from the nineteenth to the twentieth century, the first media conglomerates were born. William Randolph Hearst (d. 1951) is said to have been the first media mogul, owner of dozens of newspapers across the United States and a movie studio as well. The second largest media conglomerate currently in the world in terms of revenue is the Disney Company, outgrowth of a concern founded by Walt and Roy Disney in 1923 and listed on the New York Stock Exchange since 1991. The largest is Comcast, with over 100 000 employees and a predominant influence in virtually every market and genre, owner of cable networks, news and sports programs, a movie studio (Universal), media-related theme parks, and even, in part, a professional basketball team. Among the largest in the Asian market is the Sony Corporation, including books and electronics, which developed from a firm begun in Tokyo in 1946 by Masaru Ibuka. The power of multinational media giants to defy local norms or at least local tabus in the gathering and publication of information about individuals or things regarded as newsworthy, while propounding particular political and social visions held by their owners, has most recently been discussed in the case of Australian media magnate Rupert Murdoch.

The Internet enters the realm of the media in a series of information and communication technology (ICT) developments going from ARPANET to the World Wide Web (1969–89) and begins to assume a predominant role. The advent of cloud computing and media in streaming motivates new approaches in industries that once thrived by the sale of tangible commodities such as disks, tapes, and further back in time, records and even cylinders, while new media, social media, and open media authorship suggest new possibilities for media productivity, whose significance may only be imagined. Interconnectvity enables scientific and scholarly collaboration while introducing new challenges. With governments increasingly pursuing online activity due to the potential for policing and corporations interested for purposes of, movements for open information, open source, open data, and the like have raised an increasingly insistent voice in favor of public interests, however vaguely defined. E-democracy defines a movement to utilize ICT resources for instituting consensus-based societies motivated by greater citizen participation than is customary in current representative systems (Macintosh, A., 2006).

The so-called 'digital divide' defines the boundary between areas of the Earth reached by the latest advances in ICT and those left behind. Whether a 'knowledge society' (in the terminology of Peter Drucker, 1969) or an 'information society' (Daniel Bell, 1976) is possible, where the electronic media do not reach, may be a matter of concern for overall global development.

Historical Change

Theories of media change date at least to Giambattista Vico (1725), who attempted to draw conclusions regarding the

recurrent cycles experienced by human societies from time to time and found that the communication of information played a key role. Reading back into the earliest periods of ancient society, he posited an initial 'poetic' stage of primitive cruelty without rational thought or articulate speech, where authority was believed to proceed directly from divine fiat. In the subsequent 'heroic' or aristocratic stage, political discourse was intentionally concealed from the purview of the general population and kept as a sort of professional monopoly among the ruling elite. "Naturally continuing to practice religious customs, they religiously continued to keep the laws mysterious and secret (this secrecy being the soul and life of aristocratic states)." Discussing political interests only among themselves, the aristocrats decided generally for the good of the territory because of their private interests as proprietors. In the 'human' stage, by contrast, everyone was required to know the law and to judge private utility in relation to society. "Naturally open, generous and magnanimous (being commanded by the multitude, who naturally understand natural equity) … [the nations] went on to make public what had been secret." Such, he believed, had happened in Europe within recent memory.

Modern media historians usually speak of three fundamental developments between early and modern times, namely, the advent of the handpress; the application of new technologies, including steam power, cinematography, radio, and television; and most recently, the emergence of ubiquitous computing and the Internet. Whether such developments can plausibly be denominated as 'revolutions' is among the issues that concern a body of theoretical work regarding historical change. In this connection, Schumpeter's notion of 'creative destruction' and Thomas Kuehn's notion of paradigm shift may be relevant, even though not originally intended to apply to media history.

Proponents of the 'revolution' thesis include Marshall McLuhan (1962) and, more recently, Frederic Barbier (2000). Peter Burke and Asa Briggs (2002) sound a cautionary note, eschewing any metahistorical pattern-seeking, in the light of the stops and starts, the movements back and forth, the geographical inconsistency, and the subcultures of nonconformity that will fail to be noticed in any period if a metahistorical perspective is rigorously applied. Adrian Johns (1998) and Andrew Pettegree (2010), analyzing the specific case of print, emphasize the aspects of continuity with the use of script, questioning the fixity usually attributed to print.

Some change theorists, such as Lewis Mumford (1934), adopt a form of technological determinism ultimately harking back to Karl Marx, although in the version of David Landes (1969), this approach supports an account drawing attention to the advantages of free-market capitalism. Curiosity- and demand-driven inventions, he maintains, have built the Western industries that provided the goods characteristic of a modern lifestyle. In later work, Landes (1998) complicated his earlier model of economic development by adding the effects of variables such as culture, religion, geography, and so forth to explain inequalities and unequal outcomes within the world economies. Joel Mokyer (1990) claims to bring an evolutionary and systems-analytic perspective to the theory of technological change. Technological systems, he notes, like all systems, must have some built-in stability, but when resistance to change prevents creativity or the acceptance of innovations, this may help explain some of the differences in media development.

More along the lines of a sociological determinism, Niklas Luhmann (2012) posits, "Societal communication produces various media/forms depending on what problem is to be solved." For instance, printing was an extension of the rationalization of book production already begun in the Middle Ages and basically tended to allow societies to take full advantage of the system-differentiation potential unleashed by the advent of writing. The age of electricity freed communication still further by placing energy production in a separate realm from the communication of messages. Finally, computer-assisted communication tends in the direction of a world society.

Theories of Impact

That the media, in each period, have been agents of change is self-evident; therefore, analytical distinctions need to be made. Fernand Braudel (1981) remarked that the printing press, for instance, "expanded and invigorated everything." Exactly which changes are to be credited to which media in a given period and how the change was experienced and by whom are the chief concerns of a body of theoretical and empirical work regarding media impact. Elizabeth Eisenstein (1979) has made a suggestive case for the role of print in triggering the Renaissance, the Protestant Reformation, and the so-called Scientific Revolution. Subsequent work has attempted to validate such claims in the light of other plausible causes for the observed phenomena.

A highly influential analysis, sometimes known as the liberal thesis, suggests that media across the ages have ultimately contributed to the emergence of democratic societies and a responsible electorate (Lasswell, 1948). Whether a clear line of development can indeed be traced from the media of the past to those in modern democracies is open to debate. Since the 1980s, the liberal thesis has largely been superseded by public sphere theory, especially in the form expressed by Jurgen Habermas ([1962]1989). This theory is particularly concerned with the emancipatory role of the press in given periods, sometimes pointing to the benefits accrued to particular social strata or classes. According to Habermas, between the seventeenth and eighteenth centuries in Europe, wherever there was relatively free access to information, "men making public use of their reason" among the emerging bourgeoisie, tending to the formation of a collective will, replaced a previous regime of public expressions in regard to power and authority confined to official celebrations demonstrating ('representing') the position of the monarch and court vis-à-vis the rest of the populations. Variations on this pattern may occur from place to place due to the presence or absence of a free press and a substantial bourgeoisie. Some proponents of this theory have been more sanguine than Habermas was about whether the 'bourgeois public sphere' (his terminology) was a wholly satisfactory outcome. A feminist version of the theory draws attention to the emancipatory role of the media in certain periods viewed from a gender perspective (e.g., Gelbart, 1987).

Criticisms of such views have drawn attention to the inapplicability of the category of 'representative' public sphere, in

particular early modern contexts (Michel Reinders, 2010), or to the different local and regional timing of the transition away from the 'representative.' More general criticisms have questioned the focus on the news media as the main constituent of a public sphere, pointing out the many other interaction contexts that may contribute (Bloemendal and Van Dixhoorn, 2010). In addition, when information becomes a commodity, industrial strategies and political agendas may produce manipulations and distortions disruptive to collective will formation. Public spheres, whatever and wherever they may be, surely contain as much knowledge as nonsense, as much reason as unreason, and as much information as propaganda so that equally predominant effects may be to reinforce prejudices and spread pseudoknowledge, when not simply narcotizing by a surfeit of information. Some works question whether women have ever indeed fully participated in the public sphere as defined in the literature (Magalhães et al., 2012). Political philosopher John Rawls (1993), on the other hand, rather than the emancipatory effect of abstracted reason in the ideal situation imagined by most public sphere theories, posited instead, as the true sphere of reasonable citizenship, the real interchange of ideas in the semipublic spaces of associational life within civil society, tending to resolve issues between real persons and among groups, which occurs from day to day apparently without recourse to coercion, organized or otherwise, not to be confused with the more restricted realm of public decision making within the institutions.

Habermas (1975) and Manuel Castells (1996) have both pointed to the legitimation crisis of late capitalism, whereby the public sphere, fragmented by the encroachment of political, economic, and social systems, no longer provides that area of public reason which obtained at the dawn of the mass media. Consequently, public reason retreats from open discussion of common issues of public concern into NGOs and voluntary organizations. Castells, for instance, points to the paradox of increasing globalization and aggregation in the realm of mass media and communications accompanied, as though in reaction, by an increasing trend toward reinforcement of local cultural affiliations, real or invented.

This would be the place to point out that in certain regimes, perhaps all regimes, the media have been said to be instrumentalized by elites, to a greater or lesser extent, for the purpose of coaxing the wider public into behaving in ways that promote the economic or political welfare of such elites. Propaganda theory attempts, either for purpose of practical use (Bernays, 1952) or for purpose of understanding (Lasswell, 1971; Doob, 1935; more recently Chomsky, 1988) or both, to identify the most effective means of utilizing the media for mass persuasion. Some critics point out that propaganda theory inevitably falls short at the moment when it fails to recognize that propagandists and their publics normally belong to the same society and may indeed be impelled by the same social forces that one side is pretending to direct. Jacques Ellul ([1962]1973) defines propaganda as the effect of a technological society embracing the entire person and tending to total integration. According to this analysis, "Propaganda stops us from feeling that things in society are oppressive and persuades us to submit with good grace." Enzensberger cautions against ignoring the manipulative potential of every type of media, insisting on the ways in which a 'consciousness industry' reinforces the essential class basis of advanced capitalism (Enzensberger, 1974).

Previous predictions about the imminent demise of television due to an advancing Internet have failed to account for the resilience of a medium that has evolved in part through on-demand programming to accommodate an increasing range of tastes and preferences on the part of viewers. More to the point have been the attacks on quality of content. Frankfurt School critics Horkheimer and Adorno ([1969] 2002) famously decried, "the impoverishment of aesthetic matter so drastically, that by tomorrow the thinly veiled identity of all industrial culture products can come triumphantly out into the open, derisively fulfilling the Wagnerian dream of the Gesamtkunstwerk, the fusion of all the arts in one work." In their view, matured on the basis of the observation of thousands of hours of programming, interesting only for its very banality, "The alliance of word, image, and music is all the more perfect than in Tristan because the sensuous elements which all approvingly reflect the surface of social reality are in principle embodied in the same technical process, the unity of which becomes its distinctive content." The only corrective could be a facetious one: "Television points the way to a development which might easily enough force the Warner Brothers into what would certainly be the unwelcome position of serious musicians and cultural conservatives." That such criticisms, quite apart from the evident hostility to a certain strand of German late-Romanticism, now appear somewhat quaintly elitist may only be due to shifting definitions of what is good taste and what is not.

If public sphere theory seems to be mainly concerned with the political aspect of the media, general systems theory at least has the benefit of taking a larger portion of the contents of the media under its purview. Such is the case because, at the most abstract level, this theory deals with societies' advancement toward ever-increasing structural complexity, suggesting a special role of the media in achieving that. Social networks, so the theory goes, set continuously shifting end points for themselves during the course of their self-reproduction and the media tend to help incorporate new information – the so-called 'feedback loops.' An advantage of this view, according to a few of its proponents, is that in this way all the behavior of collectivities – rational and irrational – can be examined equivalently, without the hazards to objectivity involved in labeling the irrational as deviant (Morin, 1977–80).

Much thought has been devoted to whether digital communications have fundamentally changed the way we think, teach, and write. Holding to a minimal effect are those, such as Robert Darnton (2009), who point out that a supposed shift to extensive and varied bibliographies, processed discontinuously, partially, and with varying degrees of attention, was already noticed in the beginning of print culture. Holding to a transformative effect are those who suggest an inevitable correlation between certain evident characteristics of the digital media and certain probable configurations that seem to turn up in the realms of thought and expression. The 'new literacy' (Coiro and Dobler, 2007) offers new possibilities to be realized by acquiring new skills.

Especially the takeoff of social media and the impact of dematerialization, reembodiment, sharing, co-construction of the self, and distributed memory have engaged a rethinking

of 1980s notions about the 'extended self' in media socio-psychology (Belk, 2013). Moreover, the prevalence of cross-border blogging has provided new insights for understanding the construction of national and ethnic identities (Rulyova and Zagibalov, 2012).

Theories of Structure and Content

The media gain cultural significance as much by the contents of their particular products as by the effect they have on audiences. They are differentiated by the ways in which they exercise these effects. Harold A. Innis (1950) characterized 'time-based media' as those, such as clay tablets or inscriptions on stone, meant to carry messages across the ages but not necessarily to the multitudes. These he contrasted with 'space-based media' capable of bearing more ephemeral messages to a mass audience. Rarely found in their pure types, he saw the first as characteristic of community-based, tradition-bound societies, while the second favored rapid change, administrative centralization, and empire.

Marshall McLuhan (1967) famously maintained, "the medium is the message." By this he meant that the tools of communication themselves, apart from the message content, profoundly shape an age. As for his own age, he was not as optimistic as were some technophiles; indeed, he remained much dismayed about the all-absorbing effects of the modern media on the individual psyche. When he said radio, telephone, and television "eliminate time and space factors in human association," "creating involvement in depth" (from Understanding Media, McLuhan, 1964), he said so with profound misgivings.

McLuhan remains a highly controversial figure. Nonetheless, media history continues to be intensely concerned with how the characteristics of particular media have impacted upon the transmission of ideas. In principle, the contents of books, films, broadcasts, and so forth can hardly be separated from these as media. However, when the content intersects with other discourses extraneous to media history per se, the more or less separate histories of literature, rhetoric, art, performance studies, film studies, and so forth may be called into play, and so also the various critical movements associated with literary deconstruction, postmodernism, post-structuralism, postcolonial studies, gender studies, queer theory, and so forth, none of which constitutes a media theory per se.

Regis Debray (2000) notes that a particular medium delivers its content not as a simple container but as an element within a system, setting the boundary conditions for the way in which such content may be received. To the special study of the 'frameworks that administer belief in that content,' he gave the name 'mediology.'

Late twentieth-century television critics such as Raymond Williams (1974) and Pierre Bourdieu (1998) have drawn attention to the structural features that have supposedly prevented the media from fulfilling their promise by limiting viewer autonomy and channeling responses. Paddy Scannell (2009) has more recently noted that the advent of on-demand programming and the density of the media landscape vitiate such criticisms, adding that the endless 'now' generated by the emerging global connectivity effectively overcomes "the time-space constraints of older transport and communication systems."

That film theory actually begins with Henri Bergson, as is sometimes said, can only be partly true, as his *Creative Evolution* (Bergson, 1911) uses the cinema mainly as a metaphor for human consciousness in general and the epistemological and physiological principles of his *Matter and Memory* (Bergson, 1912) have mostly been incorporated into media studies (by Gilles Deleuze, 1986–89) ex post facto. Walter Benjamin's view (Benjamin, [1936]1968) was arguably more influential, focusing on the psychosocial implications of the art of cinematography in the light of the role assigned to culture in the Marxian model of historical development. An age of industrialism and proletarian advance, he argued, had spawned a technology-based art form, transcending traditional values, associated with the uniqueness or 'aura' of a work, such as had predominated in the ages of the great 'artists.' The new art of cinema would not only destroy the old forms and concepts in a spirit attuned to 'the universal equality of things' but it would produce new expressions more attuned to modern tastes.

The realistic tendency in film was the object of numerous contributions to film criticism ranging from Rudolf Arnheim and Béla Balázs to Siegfried Kracauer to André Bazin. A new turn emerged in the *Cahiers du Cinema*, edited in Paris from 1951 by Bazin and others, when the contributing cinematographer, François Truffaut, propounded the auteur theory, a background for the so-called Nouvelle Vague cinema of Truffaut and Jean-Luc Godard. Structuralism, psychoanalysis, and Marxism became the magazine's dominant tendencies in the 1960s, and these entered Anglophone film theory largely by way of the journal *Screen*, published from 1969 by the UK Society for Education in Film and Television.

In recent times, widespread amateur engagement with digital media, according to Laura Rascaroli (2009) and others, has opened a new chapter not only in film history but in the history of self-expression and ego-documentation, as well as the textualizing, illustrating, narrating, and recording of personal and group experience, essentially amounting to a new practice of the media.

Research Methods

Media history has furnished compelling objects of analysis to legions of researchers, dating at least to the advent of media criticism in the sixteenth century (Garzoni, 1590). A media historiography extending from Gutenberg to modern times has experimented with the application of a wide array of empirical approaches and theoretical perspectives rooted in numerous disciplinary specializations. As far as audiences are concerned, literacy statistics exist only from the 1880s (Louis Maggiolo), based at first on signatures applied to official documents. Studies of the history of reading begin arguably with Daniel Mornet (1933) working with probate records from the late eighteenth century. Connecting particular audiences with particular media has been notoriously difficult, and more or less sophisticated semiotic approaches, drawing conclusions from media content, have continued to prevail ever since the advent of audience surveys, due in part to the absence of other kinds of evidence for audience response in the early periods.

Such, with many variations, were the approaches of the interdisciplinary Frankfurt School of social research, including Horkheimer and Adorno. The first real surveys are said to be the Payne Fund Studies (1929–33) concerning the influence of cinema on children. At the close of World War II, Robert K. Merton (1946) and his team combined empirical research with theoretical insights to study the effects of radio broadcasting on the sale of war bonds. Machine-assisted analysis has permitted survey-taking and quantification on an unprecedented scale.

A major problem for the retrospective application of some of the available social theories is that they have been elaborated in epochs when the conditions of the media were far different, and if used incautiously, may add more obscurity than clarity to the understanding of the past. An example is propaganda theory, whose use needs to take into account that previous media systems had far less potential for controlling, distributing, and excluding information than they have since the advent of modern technology, and explaining precisely how a particular propagandistic 'message' is 'diffused' by an early modern 'propagandist' (as the theories require) is notoriously difficult.

The tremendous quantities of data to be analyzed by the media historian, in the effort to grasp the changes and uniformities over time, have encouraged engagement with digital approaches. Vast databases have been created, and the texts and images from the various sorts of media have been marked up for digital processing. Numerous methods of digital content analysis have been deployed of which a prominent example, at least for text-based media, has been *General Inquirer: A Computer Approach to Content Analysis* (P.J. Stone et al., 1966). A method of qualitative analysis has been elaborated by Philipp Mayring (seventh ed., 2000). More recently, corpus-based studies, employing data mining techniques and linguistic analysis, have gained currency (on which the treatise by Andrew Hardie and Tony McEnery (2011) is particularly illuminating) not only for understanding the construction of texts but also for assessing style, sources, movement, and so forth in a comparative framework.

A particular challenge of recent research on print media, especially in regard to the more remote periods, has been to find ways of examining the contents of large numbers of publications distributed across various spatial, temporal, and linguistic boundaries in the effort to understand culturally based transmutations and transformations, as texts travel from place to place. The linguistic challenges alone have inspired attempts, such as by Roberto Valdeón, to join media history and translation studies (Valdeón, 2007).

As the products of visual and audiovisual media proliferate and the commercial demand for tools enabling management of personal and public archives becomes more pressing, much attention has been devoted to developing reliable automatic and semiautomatic systems of image and video retrieval. These systems are highly relevant to media history. Audiovisual media, such as television programming, are now analyzed retrospectively utilizing such systems, for instance, by the Key Visuals project of Peter Ludes (2001) with the collaboration of Otthein Herzog between Jacobs University and the University of Bremen, aimed at recovering the repertory of key visuals diffused to audiences from time to time around the globe, especially within news programs. The result may be a new understanding of the cross-cultural patterns and variations in the presentation of events, persons, and objects of interest to viewers in a given period. Media images, Ludes has said, "in their specific multimodal compositions, create collective (audio-) visual memories. Thereby they enhance mutual expectations and the coordination of social actions." Another challenge would regard the vast amount of visual material, not yet annotated or marked up in any way, now stored on the Web for which new approaches hold out the promise for future retrieval for purposes of analysis and study.

As the line between public and private communications keeps being redrawn, the definition of media will shift and so will the definition of what is of interest to media history. Huge amounts of personal data and commentary voluntarily vouchsafed by users and collected by social media companies, Facebook, etc., shared online and utilized for focused advertizing campaigns and the like constitute an unmatched source for understanding cultural change, social integration, identity formation, political alignment, gender attitudes, etc., so far accessible to researchers only piecemeal due to privacy protections and corporate interests. Government databases compiled from massive collection of public and private media sources originating among citizens and nonnationals alike, onshore and offshore, sanctioned by committees whose deliberations are off-limits to the public, may one day provide a key source of media history. So far, private research normally gains access to similar data only by accident or by stealth, as formal requests are routinely denied for reasons of national security. For instance, trillions of hours of random cellular telephone conversations of personages ranging from the insignificant to the significant, including heads of state and high-ranking military officials, digitized and stored, no one knows for how long or according to what classified criteria, could yield, by advanced tools of voice recognition and concept indexing, important results in terms of opinion tracking and, even with the most primitive of tools, key pieces of evidence explaining the processes of industrial decision making or the conundrums of international politics. Finally, highly reserved internal media documenting the day-to-day workings of the government agencies themselves, possibly as voluminous as all the media publicly available to private citizens if not more (Galison, 2004), are currently leaving a media trail for researchers of the future, detailing the words and deeds of persons currently protected from scrutiny by state secrets legislation supposing that no more sophisticated bulwarks or privileged shredding agreements are put in place to shield them from the curious. Meanwhile, penultimate versions of technology spun off from national security agencies engaged in compiling information gleaned from high-level surveillance of millions of homes and offices, now commercialized as Sqrrl, offering "secure database software for Big Data applications," may be of some use in analyzing some of the masses of data that are currently available to researchers, especially considering that it "supports a wide variety of analytics including search, SQL, and graph."

The need to archive and manage what is and what will be known of the media becomes all the more urgent, as the history of the media is ultimately the history of us.

Abstract

Contemporary social movements engage in a complicated and uneasy dance with the mass media. Historically, movements have typically had their own media, controlled by movement participants and directed at the people they hoped to rally to their cause. Where mass media were once peripheral to understanding movements, in the last half-century, with the rise of television, they have become central. It is no longer possible to understand the actions of contemporary movements without understanding the nature of the movement–mass media transaction.

This article introduces the reader to the critical role of mass media for social movements as sites of contest and indicator of broader cultural changes in the civil society. The article describes the role of mass media in the social construction of meaning that shapes language use and political consciousness of individuals in society. The concept of media structural opportunities is presented and discussed, and the strategic implications of the constant interaction of social movements with media are discussed.

Contemporary social movements engage in a complicated and uneasy dance with the mass media. Historically, movements have typically had their own media, controlled by movement participants, and directed at the people they hoped to rally to their cause. Where mass media were once peripheral to understanding movements, in the last half-century, with the rise of television, they have become central. It is no longer possible to understand the actions of contemporary movements without understanding the nature of the movement–mass media transaction.

Social movements are fields of collective actors maintaining a sustained challenge to institutional practices, policies, and power arrangements and/or to cultural codes by mobilizing people for collective action, at least some of which is contentious. Many of the above terms require some brief elaboration. Collective actors (generally called social movement organizations) are typically formal with designated officers but may also include more informal advocacy networks, often grouped around some publication or think tank. The field of actors has some means of sustaining the challenge over time; a one-time march or rally does not make a social movement. Challenges may have a strong cultural component as well as representing efforts to change institutions and policies. In democracies, there are institutionalized and prescribed ways of citizens exercising influence on policy using the legal system, electoral system, and the peaceful petitioning of public officials ('lobbying'). Unless at least one actor in the relevant field is engaged in other, more contentious forms of collective action – be it rallies, demonstrations, publicity campaigns aimed at embarrassing opponents, boycotts, strikes, violence, or various other types of unruly behavior – it does not qualify as a social movement. The role of social media has changed the role of social movements. It has changed the hierarchy of the media landscape as citizen journalists have emerged and stoked the fires of a social movement. Most notable in the intersection of social media and social movements was the Arab Spring. Facebook and Twitter became as influential as the mainstream media.

Role of the Mass Media

Social movement organizations typically make use of direct media in the form of newsletters to members and, increasingly, e-mail. In addition, there are often alternative media read by many of their constituents that report sympathetically on their activities. However, they cannot afford to ignore general audience mass media for several reasons. First, the mass media provide a master forum in the sense that the players in every other forum also use the mass media, either as participants or as part of the gallery. Among the various forums of public discourse, the mass media provide the most generally available and shared set of cultural tools. Social movement organizations must assume that their own constituents are part of the mass media gallery and the messages their would-be supporters hear cannot be ignored, no matter how extensive the movement's own alternative media may be.

Second, mass media forums are *the* major site of contest politically in part because all of the potential or actual sponsors of meaning – be they authorities, members, or challengers – *assume* pervasive influence (whether justified or not). The mass media often become the critical gallery for discourse carried on in other forums, with success measured by whether a speech in a legislative body or other venue is featured prominently in elite newspapers or in television news coverage.

Finally, the mass media forum is not simply a site of contest and indicator of broader cultural changes in the civil society. The meanings constructed at this site influence changes in language use and political consciousness in the workplace and other settings in which people go about the public part of their daily lives. When a cultural code is being challenged successfully, changes in the media forum both signal and spread the change. To have one's preferred understanding of a policy issue increase significantly in mass media forums is both an important outcome in itself and carries a strong promise of a ripple effect.

It is useful to think of mass media output in terms of the relative prominence of competing *frames*. A frame is a central organizing idea for making sense of relevant events, suggesting

what is at issue. 'Media frames,' Gitlin (1980, p. 7) writes, "largely unspoken and unacknowledged, organize the world both for journalists who report it and, in some important degree, for us who rely on their reports." Movement organizations compete with others as sponsors of frames, attempting to promote the career of their favorite through a variety of tangible activities – speech-making, pamphlet writing, demonstrations, advertising, interviews with journalists, and the like.

Media Opportunity Structure

Social movement organizations must compete with other sponsors of frames – public officials, political parties, corporations, vested interest groups, and journalists themselves. Mass media norms and practices can sometimes facilitate movement success in this contest but on balance tend to present a series of obstacles that put them at a relative disadvantage. This media opportunity structure is one subpart of the larger political opportunity structure in which movements must operate in attempting to shape an effective symbolic strategy.

Movement Opportunities

Social movements often make good copy for the media. They provide drama conflict, and action, colorful copy, and photo opportunities. Because visual material puts a higher premium on spectacle, television is more likely than print media to emphasize it. Spectacle means drama and confrontation, emotional events involving people who have fire in the belly, who are extravagant and unpredictable. This puts a high premium on novelty, on costume, and on confrontation.

Violent action has most of these media-valued elements. Fire in the belly is fine but fire on the ground photographs better. Burning buildings and tires make better television than peaceful vigils and orderly marches. Visual spectacle is high in entertainment value. When news is a vehicle for procuring an audience to sell to advertisers, then one needs to worry about people tuning out. The media opportunity structure provides an incentive for action strategies that provide strong visual material.

Movement Constraints

Social movement organizations typically need to overcome four major obstacles in media norms and practices. The focus here is on the American news media but to the extent that the news media in other countries are similar, the same obstacles will be present. First, journalists have a strong tendency to give official frames the benefit of the doubt. In many cases, the assumptions of these officials are taken for granted; but even when they are challenged by social movement organizations, it is these challengers who carry the burden of proof. A weaker form of this argument is that journalists make official frames the starting point for discussing an issue.

Various observers have noted how subtly and unconsciously this process operates. Halberstam (1979, p. 414) describes how former television news anchor Walter Cronkite's concern with avoiding controversy led to his acceptance of the assumptions underlying official packages. "To him, editorializing was going against the government. He had little awareness, nor did his employers want him to, of the editorializing which he did automatically by unconsciously going along with the government's position."

A second disadvantage for social movement organizations stems from the daily news routines of journalists. These news routines bring reporters into regular – sometimes even daily – contact with sources representing public agencies, political parties, corporations, and other well-established groups. They rarely include regular contact with groups who are challenging the dominant interpretations of events. Social movement organizations, then, lack the routine access to journalists that are characteristic of their rivals.

Third, other media norms and practices in the United States – particularly the *balance norm* – favor certain sponsors of alternative frames. In news accounts, interpretation is generally provided through quotations and balance is provided by quoting spokespersons with competing views. The balance norm is vague and the practices it gives rise to favor certain spokespersons over others. Organized opposition is a necessary condition for activating the norm. Once invoked, there is a strong tendency to reduce controversy to two competing positions – an official one and the alternative (if there is one) sponsored by the most vested member of the polity. In many cases, the critics may share the same unstated common frame as officials, differing only on secondary issues of the most effective means of achieving particular outcomes.

The balance norm, however, is rarely interpreted to include challenger frames, even when no other alternative is available. Tuchman (1978, p. 112) argues that balance in television news in the United States 'means in practice that Republicans may rebut Democrats and vice-versa' but that 'supposedly illegitimate challengers' are rarely offered the opportunity to criticize government statements. Instead, she suggests, "reporters search for an 'establishment critic' or for a 'responsible spokesman' whom they have themselves created or promoted to a position of prominence."

Finally, there is a culture clash between the more pragmatic and cynical subculture of American journalists and the more idealistic and righteous subculture typical of movement organizations (see Eliasoph, 1998). Movements seem to demand unreasonable and unrealistic things and often have a righteousness that is unappealing to those who are living with the inevitable compromises of daily life. Movements hector people and call them to account. This means that internal movement conflicts and peccadilloes will have a special fascination for journalists, giving them an opportunity to even the score from their standpoint. As Gamson and Wolfsfeld (1993, p. 120) put it, "The fall of the righteous is a favored media story wherever it can be found, and movements offer a happy hunting ground."

Strategic Dilemmas of Movements

These characteristics of the media opportunity structure create a series of dilemmas for the symbolic strategies of social movement organizations. Movement–media communication is, to quote Gamson and Wolfsfeld (1993, p. 119), "like

a conversation between a monolingual and a bilingual speaker." The media speak mainstreamese, and movements are tempted to adopt this language since journalists are prone to misunderstand or never hear the alternate language and its underlying ideas. Movement activists often feel that something has been lost in translation. One can accept the dominant cultural codes and not challenge what is taken for granted, but for many movements this would surrender fundamental aspects of their *raison d'e tre*.

There is, then, a fundamental ambivalence and, for some, an estrangement between movements and media. Movement activists tend to view mainstream media not as autonomous and neutral actors but as agents and handmaidens of dominant groups. The media carry the cultural codes being challenged, maintaining and reproducing them. In this sense, they are a target as much as a medium of communication. But they are also the latter since one tries to speak *through* the media rather than to them. This dual media role is the central problematic from the movement standpoint and gives rise to the following dilemmas.

Publicity as Validation

When demonstrators chant, 'the whole world is watching,' it means that they matter, that they are making history. The media spotlight validates the fact that the movement is an important player. Conversely, a demonstration with no media coverage at all is a nonevent, unlikely to have any positive influence either on mobilizing followers or changing the target. No news is bad news.

Given the lack of routine access, getting attention is a necessary step in promoting a preferred frame. But the very tactics that are employed to garner this attention can detract from the preferred frame one is sponsoring. Members of the club enter the media forum through the front door when they choose, are treated with respect, and given the benefit of the doubt. Movement organizations must find some gimmick or act of disorder to force their way in. But entering in this manner, they risk being framed as crazies or fanatics and the preferred frame they are promoting may be obscured in the process. "Those who dress up in costume to be admitted to the media's party will not be allowed to change before being photographed," write Gamson and Wolfsfeld (1993, p. 122).

Weak Control Over Followers

Movement organizations face the additional dilemma that, even if they engage in strategic planning, their weak control over the actions of their followers may make it impossible to implement their plan. The media influence internal movement leadership by certifying some people or groups and ignoring others. Some media-designated leaders may have had few followers before their anointment but with their media-generated celebrity, they soon find followers. As Gitlin (1980) argues, it is precisely those leaders who are attached to followers only through their media image and are unaccountable to the rank and file who are likely to advocate the extravagant and dramatic actions that generate good media copy. This symbiotic relationship can undercut the carefully planned media strategies of more accountable leaders.

Measuring Success

A movement strategy can be judged successful if it solves two problems: gaining *media standing* and increasing the *relative prominence of its preferred frame* in mass media discourse.

Media Standing

In legal discourse, standing refers to the right of a person or group to challenge in a judicial forum the conduct of another, especially with regard to governmental conduct. The rules for according legal standing have been anything but fixed and clear; rather than a matter of clear definition, legal standing is a battle ground.

By analogy, media standing is also contested terrain. In news accounts, it refers to gaining the status of a regular media source whose interpretations are directly quoted. Note that standing is not the same as being covered or mentioned in the news; a group may be in the news in the sense that it is described or criticized but has no opportunity to provide interpretation and meaning to the events in which it is involved. Standing refers to a group being treated as an agent, not merely as an object being discussed by others.

From the standpoint of most journalists who are attempting to be 'objective,' the granting of standing is anything but arbitrary. Sources are selected, in this view, because they speak as or for serious players in any given policy domain: individuals or groups who have enough political power to make a potential difference in what happens. Standing is a measure of achieved cultural power.

Journalists operating in a news forum try to reflect their perceptions of who the key players are, but in practice, they are influenced by various other factors in choosing sources and quotes. In cultural contests, sources are often chosen because they are seen as representing a particular perspective. Rather than being seen as representative in the typical sense, they are chosen as prototypes who represent a particular cultural tendency in a compelling and dramatic way. In this sense, standing still reflects a journalistic political judgment about which cultural movements make a difference or are serious players.

Frame Prominence

If one charts mass media coverage of some issue domain over time, frames and their associated idea elements and symbols will ebb and flow in prominence. Success in gaining new advantages in cultural terms is measured by changes in the relative prominence of the movement's preferred frames compared to antagonistic or rival frames. This measure of success can be extended to other non-news forums as well. Frames can be extracted from cartoons, films, advertising, and entertainment as readily as from news accounts. The prominence of preferred movement frames can be assessed over time in such forums in the same way as in news forums.

Using these two measures, four media outcomes can be defined for movements. *Full response* means that the movement organization receives both media standing and a significant increase in the prominence of its preferred frame. *Collapse* means it receives neither standing nor increased prominence

for its preferred frame. *Co-optation* means that the group receives media standing but no significant increase in its preferred frame. Finally, *preemption* means that the challenger's preferred frame has significantly increased in media prominence in spite of the absence of media standing for its sponsor.

Media, Crime and Crime Waves

Abstract

The article proceeds by first establishing market model tendencies (over the public sphere model) as constraining factors that predominately dictate all news media decision making. The article then discusses a second constraining factor, the need to develop news content in an easy-to-use and easily understood format and structure, which leads media organizations to develop news themes. The result is a news selection process that facilitates the development of media-generated crime waves focusing typically on highly sensational crimes. The sporadic reporting of sensational crimes enables the development of moral panics.

Turn on the local news, watch for 5–10 min, and chances are high that the viewer will see at least one news item, probably more, that addresses some crime issue or reports on a criminal incident that has occurred. Flip the channel over to the national news, and also watch that for 5–10 min; the chances are also high, although somewhat lower than with local news, that the viewer sees a news item focusing on crime. Change the station yet again, this time to one of the multitude of 24-h news channels – Fox, CNN, MSNBC, and the like – and it is an almost certainty that one topic or more will deal with some matter of crime and criminal justice. If the person doesn't prefer one of the many news options offered by television and, instead, prefers print media – whether the handheld variety or a news item from the Internet – the chances are still incredibly likely that the person will be exposed to news on crime. It is additionally noteworthy that the typical news item is focused on a certain group of crimes: the sensational, and the type that affirms our worst fears about the world we occupy and our worst fears about the people who occupy the world with us.

After (or, for some, before) getting our daily dose of crime news, most of us venture out into the 'real world.' Walk up to any person or group of people, strike up a conversation about crime, and observe where the discussion goes. Ask the person or the group what crime is feared most. Chances are likely that the dialogue is dominated by talk of crimes of violence, stranger-based crime, a celebrity suspect or victim, a heinous crime, or a crime committed against a particularly vulnerable population (women or children), all of which can best be described as statistical anomalies in reference to true crime patterns and trends. Why is crime news is such a focus of news media? More to the point, why is it that sensational crimes are the focus of news media? Furthermore, why are Americans so predisposed to think of the most violent, most sensational types of offenses in discussions about crime?

This article provides insight on these questions. This article first discusses the market and public sphere models of news media production. The article then contends that in the world of crime news, the market model is predominant. Market imperatives heavily influence crime news selection processes. Organizational imperatives such as the need to package news into themes frequently create a false impression that an objective increase in a certain (marketable) offense is occurring, when, in fact, the only objective increase is in media reporting of the event type. Market imperatives coupled with the organizational realities of news production often create a sense that some individual, group of individuals, condition, or episode is a threat to societal interests (a moral panic) and contributes substantially to a culture of fear.

Market Demand versus the Public Good

A complete conceptual understanding of media behavior regarding crime coverage necessitates a discussion of media within a larger sociopolitical framework. Several notable scholars have argued that in the United States, the language and practices of business have had a pronounced impact on social institutions that, arguably, should be resistant to a dominance of business norms (Currie, 1991; Messner and Rosenfeld, 1994; Polanyi, 1957), and that mass media have not been immune from this trend (McManus, 1994; Postman, 2005). One scholar, in documenting a change in news media in New Zealand toward business-oriented principles, dubbed the shift the 'Americanisation' of news (Atkinson, 1994). Contemporary media producers consistently balance two competing ideas: media as a mechanism to facilitate civic and democratic participation of citizens in social and political discourse, and media as a tool to generate profits for corporate shareholders. David Croteau and William Hoynes (2001) discuss the tension between these two objectives in their analysis of the 'market' and 'public sphere' dichotomy.

In the market model of media, the media organization is viewed as a private company that is, at a basic level, simply engaging in the activity necessary to sell a product. As such, the media organization operating in accordance with the market model views the general public as consumers who have tastes and preferences in terms of the type of news item, the content of the news item, and the style in which it is delivered. A news organization fully implementing the market model is concerned with identifying news stories that are popular among readers or viewers, focusing on the aspects of the news item that are most stimulating to the reader or viewer, and using presentation structures that are engaging and entertaining. What is deemed to be in the interest of the general public is that which is popular among the news organization's 'consumers.' Additionally, it is noteworthy that attempts to regulate the

media industry are viewed by the market model advocate as an interference with normal market processes that should be influenced only by supply and demand.

In contrast, the public sphere model conceptualizes the role of the media organization as a public resource that, while having commitments to shareholders, also is obligated to serve the public. Proponents of the public sphere model suggest that the primary purpose of news media is to engage citizens through information, education, and social integration. With this model, the behavior of media is quite different. Mass media are expected to deliver diverse, substantive content through varied structures, even if the content and structures are not completely popular with the general public. The public sphere model measures success of the mass-media organization not in terms of the level of profits generated by the organization but, instead, based on whether the media company is meeting its obligations to citizens. Advocates of this model view mass-media industry regulation as essential to protect the public interest.

Market Demand Impacts on News Content and Delivery

In considering the current state of news media coverage of crime, it is difficult to obtain evidence of influence of the public sphere model. Indications of the primacy of the market model are in abundant supply (McManus, 1994). There is strong evidence that the market model impacts media decision making in terms of media selection of crime news as important relative to other categories of news items (a between-category effect). More simply stated, news producers value crime news relative to many other types of events as options for news coverage. Content analyses of general media coverage show that news items categorized as crime news occupy an elevated hierarchal position compared to other types of news items (Lipshultz and Hilt, 2002). Also, a wealth of empirical work suggests that if one considers all of the possible criminal events or all of the possible criminal events within a particular crime type that a media organization may choose to cover (e.g., assault, rape, or homicide), certain offenses have aspects that make them more appealing to news media than other criminal events (a within-crime category effect).

While both the between-crime category effect and the within-crime category effect are important and will be discussed in this article, it is the within-crime category effect that merits the most attention. Many of the practical examples of the between-crime category effect are intuitive owing to our collective sense of crime seriousness. But when the focus is on one category of crime, the factors that a journalist uses to distinguish the market worth of one offense over another may be less commonsensical. The most powerful research technique to examine factors associated with assessments of newsworthiness within a particular crime category is to begin with a list of cases and collect news coverage data on each case. Studies utilizing this approach have measured newsworthiness in the following ways: (1) whether coverage appeared at all, (2) the prominence of the coverage (time or space devoted to the case, and where the coverage was placed in the overall news day reporting), and (3) the overall intensity score (accounting for several different indicators of newsworthiness).

Scholars studying the within-crime category effect of the market model have presented arguments and theories to explain why a particular crime news item is deemed more 'newsworthy' than other crime news items. Most of the theorizing about newsworthiness assessments has been in the form of identification of the factors that increase the likelihood of coverage of a particular criminal event. Pat Doyle of the *New York Daily News* (Chermak, 1995) suggested that a good human interest murder case is one that involves an influential or well-known figure as a victim or suspect, a victim who is capable of being presented as an overmatched target in some way, and a set of circumstances that are particularly shocking or brutal, involve multiple victims or offenders, and/or have a narrative that is capable of creating a sense of mystery or drama. Similarly, Steve Chermak (1995) asserted that journalistic assessments of newsworthiness are governed by the violent or heinous nature of the offense, demographic characteristics of the victim and offender, uniqueness of the event, qualities of the incident producers (the news agency and staff), and geographic location of the criminal event.

Sensing the lack of a concise theoretical approach to the study of newsworthiness of criminal events, David Pritchard and Karen Hughes (1997) organized the various factors identified by prior scholarship into a theoretical approach that focuses attention on the degree to which a particular homicide event deviates from the normal homicide. Although their focus is on homicide events, it is appropriate to extend their theory to understanding media coverage of other within-crime category cases. They theorized that the greater the degree of statistical deviance, normative deviance, status deviance, and cultural deviance from the normal homicide case, the more likely that news media will deem the event newsworthy. First, with respect to 'statistical deviance,' Pritchard and Hughes (1997) suggested that homicide events that are abnormal purely from a statistical standpoint are more likely to be deemed newsworthy and garner coverage. Homicides that involve a gangland component, relative to the total number of homicides in any given year in the United States, are rare; therefore, based on the notion of statistical deviance from the norm, these homicides are likely considered newsworthy by journalistic standards. Statistical deviance also has applicability to between-crime category analyses; for instance, because murder or nonnegligent homicide is such a small portion of the overall number of violent crimes committed, a murder is more likely to receive coverage.

Second, Pritchard and Hughes (1997) argued that 'normative deviance' matters in how journalists assess the newsworthiness of a homicide event. Normative deviance, at its most basic level, acknowledges differential treatment of cases in statutory law and suggests that statutory provisions legitimize differences within a given crime category and, in turn, impact journalistic assessments of newsworthiness. A primary statutorily legitimized aspect of the criminal code that sets forth principles of differential treatment concerns *mens rea* and punishment. With respect to homicide, statutory law allows for harsher punishment where the crime is committed knowingly (spousal murder with intent to collect

on life insurance) compared to a homicide resulting from reckless actions (reckless driving leading to another's death). Additionally, harsher criminal sentences are permissible when a crime involves aggravating factors and less harsh sentences are allowable when mitigating factors are present. Because these are differences that have been normalized through codification into the criminal code, those crimes involving situational aspects that are treated as more serious in the criminal code are more likely to be deemed newsworthy by a typical journalist.

Third, Pritchard and Hughes (1997) defined 'status deviance' as the extent to which a person or group of persons is different based on established social benchmarks. Because a wealthy White male, for instance, is of higher social status than a poor Hispanic woman, a crime committed against a wealthy White man is deemed more newsworthy. This is the one class of 'deviance' that is not fully explored by Pritchard and Hughes (1997) in the sense that they fail to completely account for how the social statuses of the victim and the offender interact in newsworthiness assessments. It seems that the gap between the social status of the victim and that of the offender matters tremendously, that is, whether the victim's social status is higher than the offender's or the offender's social status is higher than the victim's. The potential variations of this status deviance are much too numerous to examine here, but it suffices to say that the notion of status deviance is more complex in its form than is examined in the work of Pritchard and Hughes (1997).

Last, Pritchard and Hughes (1997) advanced the concept of 'cultural deviance' as an explanation of journalistic assessments of newsworthiness. They considered a crime to be more culturally deviant when it is considered unclean, unhealthy, or perverted relative to mainstream social norms. Crimes involving a linkage to drugs or crimes committed against a particularly vulnerable population (e.g., an elderly or child victim) are examples of culturally deviant offenses. Although there is a subjective element to the notion of cultural deviance, it is important to consider that Pritchard and Hughes (1997) conceptualized cultural deviance as something to be considered relative to the typical, reasonable person. In essence, any offense where, upon hearing of the circumstances of the crime, the average person experiences a negative emotional state (anger or desire for revenge) can be considered culturally deviant. Pritchard and Hughes (1997) reported data that supported their four-item deviance framework. Their analysis of 100 homicides committed in Milwaukee, Wisconsin, found that homicides involving White persons (status deviance), female victims (statistical deviance), or elderly or young victims (cultural deviance and normative deviance) received the most extensive coverage in the *Milwaukee Sentinel* and the *Milwaukee Journal*.

The work of sociologist Richard J. Lundman (2003) addressed the limitations discussed in this article concerning status deviance. He sought a more comprehensive framework for understanding how the demographic qualities of the victim and offender impact journalistic assessments of newsworthiness. Lundman (2003) argued that race- and gender-based typification (or stereotyping) provides journalists with ready-made and easily understood 'scripts' for potential crime news events. Race- and gender-based stereotypes provide the media professional with a beginning conceptual framework to use in filtering the substantial number of criminal events for possible coverage to determine those events that will receive coverage. The more closely a particular crime is to fitting an existing race- or gender-based stereotype, the more likely that the crime will be deemed newsworthy and marketable.

The rationale of this argument is that stereotypes about race and gender are easily understood in the market audience owing to their commonality and acceptance among the populace. According to Lundman (2003), audiences are likely to reject, as confusing, stories that fail to conform to common gender and race stereotypes. Lundman (2003) pointed to two illustrations of common stereotypes. He suggested that homicides involving an African-American offender and a White victim are easily framed in the context of White fear of minority offenders. He further claimed that crimes that involve a male offender and a female victim are easily presented as either 'male sexism' or an illustration of 'male aggression and female submission.' Empirical studies have supported this expanded status deviance framework (Buckler and Travis, 2005; Lundman, 2003).

Barry Glassner (1999) also identified a theoretical factor (not expressed by the other work cited here) to account for media decisions to report events. He suggested that events that can be framed as having a larger social significance owing to their ability to communicate an underlying social crisis are more likely to be viewed as newsworthy and marketable. Although Glassner (1999) did not expressly write that these events are also ones that can be viewed as universally impacting a large portion of the population, the implication is certainly evident. Glassner's (1999) discussion centered on media reporting of workplace violence as an 'epidemic,' the Halloween candy 'panic,' and sex offenders targeting child victims, to name but a few of the illustrations. The underlying implication is that most people are employed and work in a setting away from home that places them in contact with others and most people have or know children who trick-or-treat or could potentially fall prey to child sex offenders. Glassner (1999) used data to show how these illustrations are largely social crises that are more creations of news media than true threats to personal safety.

News Themes and the Crime Wave

The Market Demand versus the Public Good and Market Demand Impacts on News Content and Delivery sections established that mass news production is heavily oriented in the direction of the market model. This overemphasis on market imperatives creates a climate wherein news organizations overreport crime items that are statistically, culturally, and normatively deviant, and dedicate attention to criminal events that reinforce gender and race-based stereotypes. Furthermore, events that may be framed as incidents that threaten the moral fabric and normal functions of important social institutions are seen as more newsworthy. Most often, however, it is not the reporting of an event, in isolation, that is problematic. After all, it is rather common knowledge that news media have a thirst for the sensational and abnormal

event. The adages "If it bleeds, it leads," and "If a dog bites a man it's not news, but if a man bites a dog, it is news," are general reference points used to describe the tendencies of mass media. Instead, the reporting of isolated events as if they represent a trend or an increased prevalence of some crime type misrepresents reality and misleads the public.

Mark Fishman (1978) referred to this process of reporting isolated events as evidence of a broader social ill as a news theme. A 'news theme' is defined as nothing more than a broad idea or theme that is common to a set of individual news items and that holds together these isolated news items in a package that is easily presentable and understood. He suggested that the organizational demands of news reporting place tremendous pressure on journalists and editors to package the news in a readily usable and easily interpretable format. The concept of a news theme is evident in terms of how a news organization arranges news items in a single day's news cycle, or with respect to how news items are presented over a longer period of time (e.g., a week, a month, or a year).

Fishman's (1978) analysis of news reporting by a network in New York City provides an illustration of a media-generated news theme. He observed that the station covered the following news stories in their reporting of the day's news:

- Police apprehend juveniles who mugged an elderly couple in Queens.
- Police and citizens in Queens meet to discuss crimes against the elderly.
- A feature segment on the Senior Citizens Robbery Unit.
- Police seize guns and drugs intended for warring gangs.
- Two members of a youth gang are arrested for robbery at knifepoint.
- An ROTC cadet is arrested in the stabbing to death of another cadet.
- An audit of NYC finds police have been mishandling funds.
- The NYC police union is working on its contract at the same time that laid-off firemen and subway cops will be rehired.

In this news segment, there are three broad themes communicated to the viewer: crime against the elderly, crime committed by young people, and city budgetary issues. Key to understanding the concept of a news theme is that the probability that any of these individual events is reported increases substantially because the events have the potential to connect to other events that, taken together, are capable of conveying a message concerning a broader issue. Fishman (1978) further asserted that news media reliance on generating news themes creates an unintended consequence that is antithetical to the purpose of journalism: in organizing information in this way, the journalist's search for knowledge produces an outcome of not fully knowing about the isolated events because, in the processing of the packaging, the isolated news items are devoid of true context.

Fishman's (1978) analysis also provided evidence that a news theme developed over the course of one day's news cycle can take on a dynamic life of its own, influencing media reporting for weeks or months. His study showed that the theme of crime committed against the elderly was evident in news reports in New York City for a 7-week period. Prior to this substantial wave of media coverage, the news organizations in New York City had covered crimes against the elderly at a pace of one news item every 2 weeks. The 'crime against the elderly wave' was, however, completely a media-generated phenomenon. Official data were analyzed and showed clearly that the news media's increased attention to the issue did not correspond with any real increase in this type of crime. Thus, many of the perceptions that citizens may experience from their consumption of news are based purely on media behavior, not on any real trend. In this regard, a 'crime wave' is defined by Fishman (1978) as little more than sporadic social awareness of crime. Any particular conclusion drawn concerning crime prevalence or social context that is based on news media depictions is likely most appropriately characterized as "things of the mind" (p. 42).

From Market Tendencies and News Themes to Moral Panic

The organizational constraint on news organizations in the form of market pressures and the need to package news in a format and structure that are easily presentable and understood by citizens have major consequences. These organizational demands have the potential of generating panic among the populace that creates pressures on political leaders to respond. The work of several scholars, including Stanley Cohen (1972), Barry Glassner (1999), and Russell E. Ward (2002), has discussed the processes and intricacies of panic. Cohen (1972) coined the term 'moral panic' to describe a social circumstance where a "condition, episode, person, or group of persons emerges to become defined as a threat to societal values and interests." He also suggested that a moral panic occurs when there is a gap between the actual and perceived threat, and the gap needs to be explained. Ward (2002: p. 466) further elaborated on the idea by adding that moral panic is characterized by "rapid and intense emotional fervor toward an issue that media and other social control agents call to public attention." Glassner's (1999) examination of "The Culture of Fear" extended the understanding of the development of panic to include others that journalists rely on in communicating information to the public. Noting, "Professional narrators play an important role too in transforming something implausible into something believable," Glassner (1999: p. 206) illuminated the importance of credible-sounding experts in giving credence to facts suggesting that fear is justified.

Cohen's (1972) "moral panic" concept was developed from his study of events that occurred in Canton, England, on Easter in 1964. Young adults and adolescents were hanging out on a street in town when a rumor began to circulate that a local bartender had refused to serve some young people. A fight eventually ensued, and several young people raced their scooters along the city streets. The incident culminated in the arrests of around 100 youths by police for very minor charges. The incident received coverage by several prominent newspapers in England, the United States, Canada, Australia, South Africa, and the European continent. The story also led to a news theme that was maintained for about a 3-year period in England. The press coverage used terms and phrases such as 'orgy of destruction,' 'battle,' 'smeared with blood and violence,' and 'screaming mob' to describe the behavior

of the youth involved. The news media distorted the amount of property damage and the number of youths on scooters.

Cohen (1972) analyzed not the behavior of the youth involved but the reaction to the event by media and officials. In developing the concept of moral panic, Cohen (1972) started with the basic presupposition that behavior of an individual or group is defined by media and officials in a sensational and stylized manner to communicate that the behavior represents a threat to existing societal values. The behavior is, in some instances, novel, but, in many cases, it is behavior that has long existed but is receiving more attention. In defining the behavior, the news media convey a very simplistic narrative steeped in stereotypical assumptions. It is at this point that media, officials, political figures, special interest groups, and experts can do and say things that prevent the panic from resonating, or further developing. If these groups, instead, do things to further advance the panic, members of these groups generally begin a process of prescribing diagnoses and recommending solutions. And, often, the diagnoses or solutions are an exaggerated response that is disproportionate to the realities of the event, condition, or episode, or they reduce further the civil rights of certain groups in society who are, quite often, already marginalized.

Gary Potter and Victor Kappeler (2006) argue that the response of the media, the US government, and the public to drugs is one of the most powerful moral panics in the history of the nation. While not specifically referencing the work of Cohen or using the term 'moral panic,' investigative journalist Dan Baum (1996), in his book *Smoke and Mirrors: The War on Drugs and the Politics of Failure*, provides powerful insight supportive of the contention that this constitutes a moral panic. Craig Reinarman and Ceres Duskin (1992) analyzed the *Washington Post* story of, and public reaction to, a fabricated 8-year-old heroin addict named 'Jimmy,' pointing out that the editorial staff of the paper and officials in the Washington, DC, area failed to question some of the most basic assumptions made in the story and, instead, gave credence to a stereotyped version of drug use. Ted Chiricos (1998) documented that the crack cocaine 'epidemic' in the 1990s was a moral panic. He showed that the attention dedicated to cocaine by media occurred at a time when use was actually declining. He attributed much of the 'panic' to the dominant theme of the coverage at the time: that the problem was spreading to previously 'safe' areas and that the issue would inflict children.

Although drug panics have been among the most prominent of moral panics, this is not to downplay the incidence of other moral panics. Scholars have identified a number of moral panics. Kathyrn J. Fox (2012) argued that the interaction between local and national news contributes to the sustainment of a moral panic concerning sex offenders that has transformed into an attack on judicial sentencing discretion. Ronald Weitzer (2007) concluded that many of the claims appearing in news media and made by officials and other experts concerning prostitution are unsubstantiated. Donna Killingbeck (2001) showed that the news media constructed a moral panic focused on school violence. Joel Best and May M. Hutchinson (1996) analyzed the presentation of gang initiation rites in media discourse and showed that media depictions invoke images of conspiratorial deviance to a degree not present in actual gang initiations. Joel Best (1991) presented evidence that news media reporting of highway shootings contributed to a short-lived moral panic.

A potential contributing factor to the origination and maintenance of moral panics is the reliance of news media on official sources of information. Kevin Buckler et al. (2008) have characterized the media and official crime sources as being 'coupled,' meaning that both the media organization (profit motive) and the government agency (public relations motive) have an interest in the coproduction of crime news to the public. These researchers also presented data showing that in two major newspapers – the *New York Times* and the *Washington Post* – quotes from or references to official sources of information appeared much more than quotes from or references to professors and nonacademic researchers with much less of an interest in furtherance of the crime item to the point that a moral panic develops. Additionally, concerning is that other scholars have reported data showing that the type of source quoted or referenced is related to the balance of information or the ideological slant of the story (Beckett, 1995; Welch et al., 1998).

Future Directions and Conclusions

This article has broadly addressed the issue of media, crime, and crime waves. Crime waves are presented as media creations resulting from sporadic coverage of isolated events that journalists perceive as marketable and that are covered as if they are evidence of some underlying trend or social ill. Future research should address several questions that remain unexplored and should examine several of the assumptions that journalists seem to make in selecting news items for coverage. One of these assumptions concerns what journalists perceive to be newsworthy and marketable, especially as it pertains to crime in general as a preferred news item for consumption and the status deviance concept identified by Pritchard and Hughes (1997). No firm body of scholarship has questioned in a systematic and fundamental way the assumptions made by journalists concerning what the public wants and, by extension, what is marketable. In essence, no body of work has questioned, as it pertains to crime coverage, whether the public is consuming the product because it is what is being produced, or whether, given viable options, the public would choose something else. Research has also yet to fully consider how changing US demographic characteristics will impact journalistic assessments with respect to status deviance and interactions between victim and offender characteristics.

Another very important avenue for future research concerns how the new 24/7 media age will impact, on the local, state, national, and global levels, coverage concerning news themes, the generation of crime waves, and the sustainment of crime waves into moral panics. The recent work of Kathyrn J. Fox (2012) is particularly instructive. She discussed how the interaction between local and national coverages sustained a moral panic focused on sex offenders. Local news was reinforced by national coverage and produced a panic that attributed blame to the 'lenient' sentencing practices of

judges. The potential exists that the new media age presents the opportunity for crime news themes to last longer, generating more powerful crime waves and sustainable moral panics.

Abstract

This article examines the impact of the media on audiences and society from two perspectives. The *traditional* approach examines how different media outlets (e.g., newspapers, radio, and television) impact on how audiences perceive the information contained in the outlet or how the audiences use a particular outlet through the media. The *contemporary* approach examines how the media are *used by others* to change attitudes and beliefs. Both traditional and contemporary approaches to media effects help to better understand how the media – and those who use it – influence people and society.

The question of whether the media really have an effect on some group of people has been studied for some time. Trying to define what 'media effects' are is not simple in today's increasingly complex media milieu, but typically definitions are focused on either what the media *does* to an audience or *how* that audience uses the media. One of the earliest media effects models was the 'hypodermic' model that posited that the media could affect changes in attitudes, beliefs, and ultimately behavior. The model, however, failed to take into account individual beliefs and uses of media. Later models have focused on how dependent people are on the media for either information or specific uses of the media. We classify these models as 'traditional.'

A second approach to media effect models, with a more persuasive and less passive overtone, has come into play. This phase, which we classify as 'contemporary,' focuses on specific models that help to understand how the audience can be persuaded into changes in attitude, belief, or action. While the traditional models have focused on the *outlets* – newspapers, magazines, radio, television, and now the social media – the contemporary models focus on *mediating factors* in the *outcome* of the media effects (Stacks, 2010; Stacks and Michaelson, 2011).

Traditional Media Effects Models

Agenda Setting

The idea of agenda setting can be traced back in the 1920s when Water Lippmann (1992), journalist and social commentator, argued in his *Public Opinion* that people were not capable of directly experiencing the bigger world, thus had to rely on the images and messages constructed by news media to form perceptions. Bernard Cohen (1963) refined Lippmann's ideas by pointing out that the media do not tell people what to think, but what to think about. Maxwell McCombs and Donald Shaw (1972) first put this idea to empirical test by comparing news media agenda and public agenda during the 1968 US presidential election. Their study found strong correlations between the prominent issues of the news media and the leading public issues. This initial effort established what is known as the agenda setting theory, since which more than 400 empirical investigations have been conducted and published.

Although agenda setting originated as political communication studies, its research scopes and applications extend beyond political settings to a wide range of public issues. Furthermore, researchers have examined the agenda-setting role of news media from the 'attributes' perspective, as compared to the traditional agenda of 'issues.' Often referred to as a second level of agenda setting, the attributes agenda setting emphasizes on the prominent characteristics and traits of objects, which composed and defined the agenda. While the first level of agenda setting is the transmission of object salience, the second level is the transmission of attribute salience (Valenzuela and McCombs, 2009).

Attribute agenda setting converges with framing theory in that they both draw attention to how particular attributes dominate – or frame – the way certain topics are addressed among publics. A media frame is a "central organizing idea for news content that supplies a context and suggests what the issue is through the use of selection, emphasis, exclusion, and elaboration" (Tankard et al., 1991, p. 3). This definition of framing converges with attribute agenda setting by emphasizing how the media picture certain topics through the news contents. Another approach of framing diverges from agenda setting by defining frames as overall principles that become socially accepted over time (Valenzuela and McCombs, 2009). The similarities and differences between agenda setting and framing are among the most discussed and investigated theoretical connections in the communication field.

Meantime, as the evidence for mass media's impact on setting public agenda accumulated, by the 1980s, scholars began to ask the question that "If the press sets the public agenda, who sets the media agenda?" (McCombs, 2005, p. 548) Three elements were prompted as key influencers for media agenda: the traditions and norms of journalism professions, daily interactions among news organizations, and news sources and their interactions with media (McCombs, 2005).

In addition, a large body of research has looked into the consequences of agenda-setting effects on attitudes and behavior. Among all, scholars have identified three distinct consequences: forming opinions, priming opinions by emphasizing on particular issues, and shaping opinions by emphasizing on particular attributes; these consequences further lead to behavior changes.

Cultivation

Cultivation theory examines the long-term effects of television viewing on viewers' conceptions of social reality. Cultivation analysis initiated as part of the Cultural Indicators Project founded by George Gerbner in the late 1960s. The central hypothesis of cultivation analysis is that people who spend more time watching television are more likely to perceive the real world in a way as most commonly depicted in television messages, as compared to those who watch less television, but are otherwise comparable in major demographic features (Gerbner, 1969).

Television is the most pervasive and constant learning system in society. Cultivation analysis approaches television as a message system with aggregate and repetitive patterns of images, the contents of which were absorbed by viewers over long period of time. Different from the then traditional mass communication research, which focused on the effects of individual messages, episodes, series, and genres on immediate attitudes and behavior changes, cultivation analysis emphasizes the general and pervasive outcomes of cumulative television exposure (Signorielli and Morgan, 2009).

Findings of nearly four decades of cultivation research on television message systems have unveiled a 'distorted' reality: exaggerated crime rates, overrepresentation of violence, gender-role stereotyping, nontraditional family composition, the 'mean world syndrome,' and so on (Morgan et al., 2009). This misshaped, yet repetitive represented 'reality,' gradually dominates the worldview of heavy viewers, who rely on television as their main source of beliefs and values.

As a primary storyteller in our society, television not only impacts on individual ideologies, but also influences society as a whole as the fundamental manifestation of the mainstream culture. Among heavy television viewers, the relatively common outlooks and values cultivated by television become the dominant or mainstream culture of that society, despite individual differences. The notion of *mainstreaming* refers to "television viewing may reduce or override differences in perspectives and behavior which stem from other social, cultural, and demographic influences" (Signorielli and Morgan, 2009, p. 113).

Some of the major aspects in cultivation studies have examined television's influences in areas such as violence, gender-role stereotypes, health, family, and most recently, online gaming and psychological health implications (Signorielli and Morgan, 2009).

Spiral of Silence

The Spiral of Silence model was raised by German researcher Elisabeth Noelle-Neumann (1984), through her observations and following studies of public opinion of the 1965 political election in the Federal Republic of Germany. According to Noelle-Neumann, Spiral of Silence is a process that "observations made in one context (the mass media) spread to another and encourage people either to proclaim their views or to swallow them and keep quiet until, in a spiraling process, the one view dominated the public scene and the other disappeared from public awareness as its adherents became mute" (Noelle-Neumann, 1984, p. 5).

Based on the assumption that individuals have opinions, the Spiral of Silence model is also built upon the contention that individuals have an innate fear of social isolation. To publicly express an idea that is unpopular or against social norms is incompatible and risky. As a result, individuals constantly monitor their environment, looking for cues that form the majority opinions (Salmon and Glynn, 2009). Mass media, in this sense, function as the predominant source of cues that construct the 'majority' side of an issue or opinions, through the use of repeated and reinforced messages and images.

While agenda setting theory focuses on media effects on the micro-level, the Spiral of Silence model is more concerned with the macro-level, long-term consequences of the public agenda. Consequently, those who hold the minority viewpoints become more reluctant to express their opinions. Over time, as fewer people speak out the unpopular sentiments, such opinions slowly fade away and eventually disappear from public discussions. The majority opinions, on the other hand, increasingly gain confidence and become more pervasive through society, eventually becoming social norms and policies.

The principles of Spiral of Silence have been massively applied in political campaigns. Political parties or advocacy groups strive to increase through the media their stances on issues to strengthen the perception of confidence. Different strategies are employed to demonstrate the magnitude of support to attract media coverage, which reinforce the impression that the party or advocacy group's viewpoints are dominant and winning.

The Spiral of Silence model, however, is somewhat controversial in that the whole model has never been subjected to a comprehensive empirical test (Salmon and Glynn, 2009). A good part of this may be because that the Spiral of Silence is a slow-going process, which can take up to decades to emerge. Empirical testing of the whole model will be extremely time-consuming and expensive. Yet, researchers are continuing to inquire into this phenomenon by testing through manageable time frames of its effect on society.

Uses and Gratifications

Uses and gratifications theory is based on the assumption that individuals consciously choose media and content to fulfill their specific needs. Compared with other traditional media effects research, which examined the communication process from the communicator's end, uses and gratifications take the perspective of audience use of the media (Windahl, 1981). It offers an alternative framework of media effects studies in that it asserts that individuals differ in their motives, attitudes, and behaviors related to media consumption.

In 1974, Katz, Blumler, and Gurevitch summarized the theoretical foundation of uses and gratifications research as focusing on: "(1) the social and psychological origins of (2) needs, which generate (3) expectations of (4) the mass media or other sources, which lead to (5) differential patterns of media exposure (or engagement in other activities), resulting in (6) need gratifications and (7) other consequences, perhaps mostly unintended ones" (p. 20).

The current view of uses and gratifications is grounded in five assumptions:

1. Communication behavior, including media selection and usage, is goal oriented, purposive, and motivated.
2. Audiences actively initiate the selection and use of media to satisfy needs or desires.
3. Social and psychological factors mediate behavior.
4. Media compete with other communication forms, such as interpersonal communication, to satisfy audiences' needs.
5. People are usually, but not always, more influential than media in this process (Rubin, 2009).

Early uses and gratifications research commenced in the 1940s, when several studies investigated why people used certain media formats, such as listening to radios (Papacharissi, 2009). In the early 1970s, researchers started to identify the motivations of media usage, and how media were used to gratify social and psychological needs (Rubin, 2009). For example, McQuail et al. (1972) observed and categorized that people sought gratifications from watching television for *diversion* (to escape and seek emotional release), *personal relationships* (companionship and social utility), *personal identity* (self-expression, reality exploration, and value fulfillment) and *surveillance* (to acquire news and information).

Extant uses and gratification research has examined media usage and consequences in various formats, including soap operas, news programs, VCR, talk radio, cable TV, magazine, channel surfing, tabloid reading, reality TV, and religious television (Papacharissi, 2009). Rubin (2009) summarizes current research areas, as generally following seven directions: (1) media-use motivations and association with attitudes and behaviors; (2) motivations across media and with new media; (3) social and psychological circumstances of media use; (4) gratifications sought and obtained; (5) variations in motives and exposure in affecting outcomes; (6) theoretical extensions with other communication perspectives; and (7) motivation measurement.

Contemporary Media Effects Models

Traditional models such as agenda-setting have served the academic community well and provided a useful framework for analysis; however, like many models, older ones may not always be able to anticipate newer aspects of media and its effects, and have, in some cases, generated conflicting results. Such changes in the media and people's accessibility to and understanding of it, often result in the need for newer models and means of analyzing media effects. Many of the more traditional means of understanding them may not take into account concepts and variables that scholars now consider to be part of the process of analyzing media effects; thus, a discussion of the Elaboration Likelihood Model (ELM) and the concept of Third-Party Endorsement is important to gain a full understanding of the scholarship surrounding the concept of media effects.

Elaboration Likelihood Model

Among the more prominent and important of the newer theories to explain media effects is the Elaboration Likelihood Model or ELM. Initially proposed by Richard E. Petty and John Cacioppo (1986, 1996), the ELM is principally concerned with explaining the way people process *persuasive* messages and how that causes their attitudes to shift over time. Before the creation of the ELM, much of the research on attitude change had found contradictory results, so the ELM was proposed as a way to explain these conflicts. The model focuses on the processes by which the source, message, and receiver variables influence attitude shifts in people, and it suggests that the change may occur either through what is termed the central or peripheral processing routes (Booth-Butterfield and Welbourne, 2002). By examining these two internal processes in message receivers, the ELM can anticipate and predict variables which impact the effectiveness of message persuasion in the audience. Additionally, the ELM anticipates that people have a motivation and desire to hold correct attitudes but can neither process nor ignore every persuasive argument they encounter (Cacioppo et al., 1986).

The advantage of using the ELM approach to media effects comes from its ability to gauge an audience's general knowledge and experiences and, through some of the more traditional media effects models, explain how the media – where most people perceive it as credible information sources and receive gratifications through its use – impact on society. In addition, adding the knowledge of how the media set the agendas and influence minority voices in a culture, the ELM provides a source-based approach to media effects, most often through advertising and public relations endeavors.

In the ELM, *central route processing* refers to the conscious and purposeful consideration of an argument based on an individual's knowledge and experiences, and the idea that they are generating positive or negative thoughts as a result of the communication (Petty et al., 2009). Part of this process is the consideration as to whether or not the information being communicated is worth considering in the first place. If the information is determined to be worthy, then it will travel through central route processing. As Petty et al. (2009) note, the kind of information judged to be important will depend on both the situation and the person; for example, one person may find a moralistic argument on an issue worth considering, while another might be more likely to think about a legal argument. Any change in attitude as a result of central route processing will be subject to internal scrutiny by the individual, so sound, well-constructed messages should create positive thoughts about the particular issue, resulting in the message being perceived as more persuasive, while the converse is also true (Booth-Butterfield and Welbourne, 2002). Additionally, the ELM anticipates that individuals who engage in extensive thinking about the issue presented to them will have a strong association between their attitudes and behaviors, lending even more importance to the active cognitive processing that accompanies central route processing (Cacioppo et al., 1986).

If information is not processed via the central route, it may be processed in the *peripheral route*. The peripheral route does not subject the information to as much careful consideration and thoughtful analysis as does the central route. In this way, the peripheral route can be considered to be a shortcut in cognitive processing, which people employ if they have little interest or ability in processing issue-relevant messages (Petty et al., 2009). As a result, attitude change based on peripheral route processing will take place because it is either associated positively or

negatively with outside cues that may or may not have any relation to the actual message, not as a result of careful consideration of the message (Petty et al., 1983).

An example of an outside cue would be the environment where the individual received the message – if they were comfortable they might process the message in a more favorable way. Another example would be the use of third-party expert to deliver the message with whom the audience has a strong favorable or unfavorable opinion, which could cause the receiver to make a decision on the message without careful consideration. In addition to using outside cues as a catalyst for decision making, an audience member may not consider all of the arguments presented, and may consider only one or two of six arguments presented, resulting in a less thoughtful decision (Booth-Butterfield and Welbourne, 2002).

Since peripheral process decisions are not based on a careful and comprehensive consideration of arguments, generally, attitudes formed as a result are not as strong as those formed via the central route, making them shorter in duration, easier to change, and less predictive of behavior (Booth-Butterfield and Welbourne, 2002). This idea that the simple cue processes underlying the peripheral process can dissipate over time has given rise to a variety of theorized effects impacting attitude generation, including the 'sleeper effect,' which implies that the influence of a discounting cue given for a message will decrease over time, allowing the message to increase in effectiveness (Petty et al., 2009). In this case, the message would have to be carefully constructed initially and then the discounting cue would be peripherally noted. The idea of peripheral processing causing a sleeper effect is reinforced by applying the differential decay hypothesis, which states that the effect will occur if the impact of the discounting cue dissipates more quickly than the original message's (Pratkanis et al., 1988). However, the order of the source cue and the discounting cue are important, since the discounting cue preceding the source cue will not typically result in a sleeper effect (Pratkanis et al., 1988).

ELM shares many qualities with another model developed around the same time. The *Heuristic-systematic model* (HSM) was originally proposed by Shelley Chaiken (1980, 1987), and it similarly proposes that people process messages in two ways: heuristically and systematically. Information processed systematically will be examined for its relevance to the person's tasks and the validity of the information will be evaluated based on prior knowledge of the issue, while people processing information heuristically will focus on simple cues and rules that associate a position with validity (Todorov et al., 2002). Systematic processing then is more deliberate and conscious, while heuristic processing tends to be more automatic and unconscious (Chaiken et al., 1989). The HSM assumes the primary goal of receivers is "… to assess the validity of the persuasive messages they encounter … and that both heuristic and systematic processing occur in the service of this goal" (Chaiken et al., 1989, p. 214). Though these processing ideas are similar to those of the ELM, the HSM holds that the methods of processing can occur concurrently. Additionally, the HSM anticipates three motivational factors which can impact a person's engagement in processing a message: desire for accuracy in judgment, defense of valid judgments, and the desire to impress others (Todorov et al., 2002). Though both HSM and ELM consider similar information in evaluating messages, the analysis of the motivations and method of process selection differ in each model, and the idea of concurrently running processes can alter the interpretation of the data.

With regard to understanding media effects, both the ELM and HSM can be useful frameworks for understanding how media can persuade audiences. By understanding motivating factors for audience members, media can work to tailor programming and messages for central or peripheral route processing, depending on the outcome they desire. Understanding which techniques are the most effective in persuading audiences, however, requires a significant investment on the part of the message originator to research the motivations and standpoint epistemology of the audience they are reaching; this is true for politicians and others seeking to use media as a persuasive tool as well.

Third-Party Endorsement

Though third-party endorsement is a relatively new concept, it is important to understanding any discussion about media effects. As it relates to media effects, the concept of third-party endorsement refers to the idea that media are supporting or endorsing the stories they report on, thus giving approval to the companies, events, people, or other concepts portrayed in the story. This approach also argues that because the source (e.g., journalist or best friend) is known to be objective and trustworthy, he or she will lend a significantly higher amount of credibility to the idea or product being reported on than if the story was delivered directly by the backer of the product or concept directly, as in an advertisement (Stacks and Michaelson, 2009). Much of the research on third-party endorsement pertains to establishing the driving force behind interpersonal advocacy of an issue, belief, company, product, and so forth leading to behavior change.

The perceived endorsement of a product, company, issue, or event by the press is really an implied endorsement, since there is rarely an explicit promotion of a product, company, or cause in a news media story. Implied endorsement refers to the idea that a source endorses the product in the story simply because he or she is covering it in one case and advocating it from media knowledge in the other case. Key to understanding this idea is the concept of intent, and it can be argued that the selection of a media story demonstrates intent to endorse on the part of the story or advocate, whether consciously or unconsciously (Hallahan, 1999). Even if this were the case, however, Kirk Hallahan (1999) notes that few studies have found large increases in audience support for issues or causes that have been explicitly supported by the media, as editorial pages in newspapers do. Even extensive, favorable product reviews, which would essentially be a positive third-party endorsement, do not increase the number of audience members expressing purchase intent toward a product as much as those exposed to an ad (Wang and Lin, 2011). The researchers, however, note that for the endorsement to be effective, it must cater to that audience's *desired communication needs*, as would be predicted by earlier media effect models.

When discussing media effects and third-party endorsement, source credibility is crucially important. In traditional mass media research, journalistic credibility is often cited as the main reason why third-party endorsement is successful in

driving interpersonal advocacy and audience behavior. Studies have found that these claims are true in some instances, but that result depends significantly on other variables associated with the message and source. Both Patricia Anderson and Sharon M. Abbott (1985) and Shelley Chaiken and Durairaj Maheswaran (1994), for instance found that the level of involvement audience members had with an issue had a direct impact on how strongly source credibility impacted their attitude toward the issue. Hallahan (1999) posits that what are perceived as third-party endorser effects might, in fact, be misclassified and the result of an audience predisposed to see media reporting favorably, which would make the consequential positive message reception a direct result of source bias. More importantly, Glen T. Cameron (1994) found that despite consciously recognizing the credibility of news organizations, people's memories generally do not retain a distinction between editorial and advertising with any great accuracy. Moderating this effect, though, is the finding that retention of information varies by media source (Cameron, 1994).

Given the variable impact that memory can have on message content, here, again, the idea of the differential decay hypothesis and sleeper effect is important. To understand the influence of third-party endorsement on persuasion and attitude, message retention is a key element. A low credibility source experiences less decay over time than a high credibility one does, provided the high credibility source had less initial impact (Cook et al., 1979). However minimally significant the impact of third-party endorsement is in persuading a general audience, the impact of third-party endorsement by media to a specific, engaged audience should not be overlooked. Some specific audiences may be more apt to be influenced by certain types of media coverage (e.g., product reviews) than others, so drawing overall conclusions as to the influence of third-party endorsement may be misleading, as it can be considerably more influential on specific audiences.

New Media

New media have brought changes and challenges to traditional media effects theories and models. Broadcast television and newspapers are no longer the only information source to which the public has access. Digital video devices, hand-held mobile wireless devices, cable and satellite TV, and Internet have increasingly become accessible and dominant in American families. The public has more choices of what to watch and read and the themes and cultures are presented by various media formats in a more diverse way as well. In addition, the trend of globalization also enables different cultures and values around the world to be heard and respected. All these new developments pose challenges to the cultivation effects of television. Although issues such as sex and violence, stereotypes, and mainstreaming are still predominant in the mass media, the cultivation effects may be less dominant as people rely more on other information options and become more open-minded.

Moreover, social media could bring revolutionary changes to the traditional media effects theories as well. Researchers have identified various motivations and gratifications for social media consumption as distinct from traditional media use (e.g., Wang et al., 2012; Muntinga et al., 2011). The distinct features of social media, such as user-generated contents, easy access, fast and wide dissemination, allow for exchanging information and expressing diverse opinions. Recent studies have found that social media have impact on the traditional media agenda (e.g., Schiffer, 2006). Eventually, some of the personal agendas widely discussed online may be picked up by the traditional media and become the public agenda. Media agenda in the new media age will be more diverse as well.

In addition, the anonymity and security offered by the new media platform offer minority groups the opportunity to form online communities to express their opinions and seek supports. Their voices are louder as they feel less isolated but more confident. Eventually, as traditional media may pick up contents from the online groups as a news source, the spiral of silence model may not be applicable.

Summary

The impact of the media on people, audiences, societies, and cultures cannot be overstated. Two of the traditional media effects models have focused on the media outlets' ability to set the agenda for discussion or change of attitudes and ultimately behavior. Two traditional models, however, focus on the decisions made by people on how that media is used or how it impacts on their ability to advocate different points of view, often leading to societal changes over time. Contemporary media effects models focus more on the media's capacity to influence through messaging and implied source endorsement of some object, whether it be an issue, a company, or simply an opinion expressed by others. The traditional models provide much insight into what the media do while the contemporary models focus more on how those media effects are obtained.

Abstract

Media effects on children as identified by resarchers may broadly be categorized into cognitive, emotional, social, and health-related outcomes. While much of this research focuses on negative outcomes like fear, aggression, materialism, and obesity, media may have positive effects on children as well such as learning and prosocial attitudes. At different ages, children are affected by media in different ways. Likewise, the most successful strategies for mitigating negative outcomes vary with children's ages.

Despite the rapid and dramatic changes in the media landscape over the past 30 years, international studies continue to suggest that children in countries as diverse as India, Indonesia, France, Switzerland, and the United States spend most of their media time with television. Thus, despite the relatively new concerns that have arisen about children's privacy and vulnerability in online interactions, much of the research and concern about media effects on children continues to revolve around a core set of outcomes. These may be categorized into cognitive/educational outcomes, emotional outcomes, social outcomes, and health-related outcomes.

Cognitive Effects of Exposure

Effects of Media on Infant Development

One genre that has emerged since the mid-1990s consists of television or DVD programing targeted to infants. Such material is often focused on language development or preliteracy and prenumeracy skills. A rapidly expanding set of experimental findings indicates that although children under 2 can learn from audiovisual representations, they learn substantially better from live interactions (the 'video deficit'). In various studies, 12-month-olds to 3-year-olds were less able to imitate novel actions seen on a video than the same actions demonstrated (in exactly the same way) by an experimenter. Recent research suggests that young children's learning from video content is improved if there are more demonstrations or longer demonstrations, if the narration is more explicit and detailed, or if familiar, liked characters (such as Elmo, from *Sesame Street*) are used rather than unfamiliar characters.

Studies that examine the outcomes of long-term exposure to educational DVDs or TV programs in the first 2 years find little evidence of positive effects and some evidence of negative relationships between language development and exposure to specific programs or to baby DVDs. One explanation for these findings may be that exposure to children's programing displaces or disrupts play–time activities and parent–child interactions that foster cognitive development. Indeed, studies suggest that such disruptions also take place when children are given electronic versions of toys rather than traditional, nonelectronic versions (e.g., an electronic book vs a board book). Research also points to negative outcomes of having adult-targeted television on in the background – in various studies, children were less focused in their play and parents were less responsive when an adult program was on. Consistent with this, a longitudinal study of 60 infants found that early exposure to background adult television (e.g., at age 1) is associated with poorer performance on measures of learning outcomes (e.g., preliteracy and numeracy) at age 4 (Barr et al., 2010). Overall, research thus far points to little benefit from electronic media use or exposure in the first 2 years of life, although there is considerable evidence of positive effects of hearing stories read aloud by caregivers. For more detail on this literature, see Kirkorian et al. (2008).

Development of Comprehension of Media Content

Even after infancy, children differ from adults in their cognitive development (including working memory capacity and attentional resources), their knowledge of the world, their understanding of how stories typically develop, and in the way they reason, make connections, and form moral judgments. Not surprisingly, research suggests that they differ from adults in the ways that they interpret and remember the stories that are read to them or that they watch on TV or in films. Although, like adults, they remember more central events of a story than peripheral events, they remember far fewer of those central events than adults do even if watching child-targeted programs. Moreover, they are less likely to focus on the characters' goals and motives, and have more difficulty connecting parts of the story to make inferences about why things occur or what will happen next. Making sense of mediated stories is made more complicated by the fact that children are also learning about the nature of each medium (e.g., about the characteristics of different genres of programing or the cues used to signal flashbacks and dreams).

As part of their developing understanding of the nature of TV programing, children change with age in their judgments about the factuality and realism of TV content. In some studies, preschool viewers responded as though they believed that the depicted characters and objects were literally inside the television set, asserting that characters could hear and see the viewers. In other studies, preschool and kindergarten children appeared to regard television as a 'magic window' onto a world where real events were taking place and where subsequent events continued to unfold and characters continue to live their lives even when the program was over. Only gradually, across

the elementary school years, do children become more adult like in their judgments about realism of programs or stories (Wright et al., 1994).

Children also develop in their ability to distinguish ads from programs and their understanding of the purpose of ads. Considerable research suggests that throughout the elementary school years, children show limited understanding of the persuasive intent of advertisers to sell products – the most common response in various studies is that ads are there to provide information about products (see Owen et al., 2007).

Effects of Educational Media Use in Childhood

Despite developmental differences in comprehension, there is substantial evidence of positive effects of exposure to educational television content among 2- to 5-year-olds. Most of the research (both in the United States and elsewhere) has focused on the effects of exposure to *Sesame Street* or the various coproductions of the program which are specifically created for a particular country or region. Overall, the research suggests that exposure to the program is associated with higher scores on literacy, numeracy, and other early learning outcomes, even for children in low- and middle-income regions or in families that are experiencing various stressors such as poverty, conflict, or maternal depression. Longitudinal research conducted in the United States suggests that early viewing (e.g., at ages 2–3) is associated with greater school readiness at age 5. In one follow-up study, early viewing of *Sesame Street* even predicted positive outcomes in high school, presumably because it initiated trajectories of school success and patterns of media preferences that continued to shape learning into adolescence (Anderson et al., 2001). In addition to the research on *Sesame Street*, there is also evidence of early learning from *Blue's Clues* (assessed across a range of early skills such as sequencing, patterning, relational concepts) and *Dora the Explorer* (divergent thinking), both of which have been aired in numerous countries beyond the United States where they were originally created.

There is less evidence of learning from educational television programing targeted toward school-aged children. Although various studies conducted in the United States have documented that children can learn from specific programs (e.g., those that teach science content), research also suggests that as children grow older and start attending school, their parents are less likely to encourage viewing of educational programs (or, indeed, even to regulate the content of exposure) and children are less likely to choose to watch educational programs of their own accord. In part, this may reflect a resistance to more learning after many hours spent in formal education each day. In one study conducted in the United States, 8- to 11-year-olds evaluated a program somewhat more negatively when told that it was educational than without such labeling.

A meta-analysis of 32 studies of learning from interactive computer games or simulations reported that (averaged across preschool, elementary, and high school students) significantly more learning took place when students used interactive media than when they had traditional classroom instruction only (Vogel et al., 2006). However, there are various studies in which there were no additional benefits of interactive media compared with traditional instruction. For example, Rosas et al. (2003) studied over 1200 first- and second-grade students from lower income regions of Chile. They found that those who were assigned to play math and literacy video games daily for 12 weeks in school performed no better than other children in the same school who did not play the games (both groups performed better than children at other, distant schools). Overall, the current evidence points to small, positive effects of educational, interactive media use, but the research base is still small enough that it is unclear what makes some programs more effective than others.

Relationships between Media Use and Academic Outcomes

Analyses of several large data sets measuring students' academic achievement, gathered in multiple countries, generally indicate a negative relationship between amount of television viewing and children's performance on standardized tests. This relationship has been observed across a variety of outcomes, including math, reading, writing, science, and social studies. However, there is also evidence that the relationship is qualified somewhat by other factors.

One key factor is the age of the child. Razel (2001) conducted a meta-analysis of six large studies (one involving standardized testing of students in 12 countries, another with students in 39 countries) providing a total sample of over 1 million students in elementary, middle, and high school. He reported that among the youngest children in the studies (those aged 9 and younger) academic achievement was highest among those who watched approximately 2 h of TV per day – watching less was associated with slightly lower achievement, and watching much more was associated with considerably lower performance. With increasing age, the optimal amount of viewing decreased substantially so that more of the viewing range was associated with decreased performance. In fact, across the various data sets Razel analyzed, the majority of children of all age groups watched more than the optimal amount of TV, and their achievement was lower than those of children who watched less.

A second factor that influences the relationship between amount of viewing and academic achievement is the socioeconomic status (SES) of the child's family, probably because SES is linked to the availability of other education-relevant resources such as books, magazines, tutoring, and other extracurricular activities. Analyses of standardized reading, writing, and math scores gathered in the United States with approximately 500 000 children suggest that the negative relationship between viewing and achievement is stronger for children from high SES families than for children from lower SES families.

Various explanations have been given for the inverse relationship between viewing and achievement. One is that viewing displaces educationally relevant activities such as homework or reading. There is some modest support for this hypothesis. In addition, there is also some evidence that viewing while studying or doing homework (something more probable among heavy viewers) reduces the amount of attention paid to the primary task and thereby reduces the quality of the work. Moreover, there is some evidence that heavy TV viewing is associated with reduced mental effort during reading.

What about academic outcomes and use of other media? In a longitudinal study of two Australian cohorts of children followed from 0- to 5-year-olds and from 4- to 9-year-olds, there was some indication that children's Internet access and frequency of computer use, as well as their frequency of reading print materials, predicted their subsequent vocabulary and language scores. A similar positive association was observed in the United States in a study of approximately 400 third-grade students – those who had access to and used a computer at home scored higher on standardized achievement tests, even after controls for parents' education, children's other media use, and their time spent reading and doing homework.

Emotional Effects of Media Use in Childhood

Children's cognitive and social development affect how they respond emotionally to the images, sounds, and narratives they see and hear. One area of research, conducted primarily by Joanne Cantor and her colleagues, has focused on developmental changes in fear responses to media content.

Fear Responses

The results of numerous studies suggest that young children (aged roughly 3–7) tend to be scared or disturbed by visually grotesque images or scary sounds, such as those often found in fantasy content, even if the actual threat implied by the narrative is relatively minimal. Material that does not contain visual or auditory distortions, such as scenes focusing on a character's anxiety or scenes in which abstract threats are conveyed via words, tend to disturb younger children relatively less. Age differences in fear responses to news stories are consistent with this pattern – in several studies, kindergarten children were much more likely to be frightened by stories of natural disasters (typically shown with scenes of destruction) than by stories of stranger violence (which typically do not have disturbing visual images). In contrast, older children, aged roughly 8–11 are no longer as focused on the perceptually striking characteristics of a situation, can understand more abstract threats, and respond empathically to the emotional displays of the characters. For a review of this research, see Cantor (2011).

Several studies of adults' recollections of media content that frightened them at some earlier point suggest that emotional responses can linger long past the initial exposure – in one study, a quarter of the sample of undergraduate students reported that they still felt residual anxiety about material they had seen as a child or adult, and a subset of those reported being unable or reluctant to engage in activities connected with the events depicted (e.g., swimming in a lake or pool having seen the shark scenes from *Jaws*).

Developmental Changes in Coping Responses

Experimental and survey research suggests that the types of strategies that help young viewers cope with frightening or upsetting material also vary with age. For children under 8, avoidance, distraction, and physical comforts such as hugging a parent or toy or getting a snack appear to be more effective than verbal reassurances that the content is not real or that there is little chance of such events happening to them. Such assurances require the ability to reassess material (a relatively difficult task, particularly under conditions of arousal and cognitive load associated with viewing something frightening) and an understanding of what probabilistic terms such as 'really unlikely' mean. As children grow older, they are more likely to have these abilities and to be able to derive comfort from verbal reassurances. An additional strategy for reducing ongoing negative affect after media exposure involves gradually desensitizing children to images, objects, or sounds related to the frightening material, under safe, nonthreatening conditions.

Future Topics: Children's Emotional Responses

There is much less research on the role of media content in fostering positive affect or enjoyment among young viewers. Research has noted, for example, that preschool viewers are often actively engaged in responding to characters on the screen, but what types of content make children feel happy or amused and to what degree the effects vary by age and by medium remains substantially understudied. Moreover, there is virtually no research on the emotional implications of children's and preteens' online interactions (whether via social networking sites, game sites, or YouTube comments). Research in England by Buckingham and his associates has explored the role of popular media content in shaping children's play and the ways in which children watch and discuss TV programs. Further work, both qualitative and quantitative, is needed to examine still further the emotional outcomes of these moments of connection around media content.

Effects of Media Use on Children's Social and Moral Development

For the past 60 years, the primary focus of concern about children's media use has been whether it makes them more hostile and aggressive and increases their chances of becoming violent adults. A parallel but much smaller body of research has focused on whether, and under what conditions, there may be prosocial outcomes of media use.

Over the years, various theories have sought to explain short- and long-term effects of exposure on viewers' attitudes and behaviors. Although most were developed within the context of media violence research, they also help explain effects of other types of content and predict other outcomes besides physical violence. These theories are reviewed elsewhere (*see* Media Effects). We proceed by briefly reviewing a relatively recent theoretical account – the General Learning Model – which integrates the key elements of earlier accounts. We then consider what evidence there is of effects of violent or prosocial content on young viewers, as predicted by the model.

Theorizing How Effects May Occur

The General Learning Model (Buckley and Anderson, 2006) proposes that media-based experiences contribute to users' knowledge structures, including their person schemata

(i.e., typical characteristics of people or groups of people) and their behavioral scripts (expectations of how people behave in particular situations). Furthermore, the theory proposes that these knowledge structures can contain links to affective states evoked by the initial experience (e.g., anger, fear, warmth) and information about what emotions are typical or appropriate in a given situation. When activated, these interconnected components (person schemata, behavioral scripts, affect, and affective knowledge) may then interact with other factors (personality, values, long-term goals, etc.) to influence people's appraisals and reactions.

How does this apply to young viewers' responses to violent or aggressive content? In the short term, exposure to violent, hostile content (whether in TV programing, in films, in music, or in video games) increases the probability that aggressive thoughts and feelings are activated and tends to increase arousal. These thoughts and feelings, combined with arousal, increase the probability that young viewers will behave aggressively. In the long term, repeated exposure to violence appears to alter viewers' beliefs and attitudes about aggression, decreasing their tendency to notice and respond to real-world pain and suffering and increasing their tendency to interpret social situations in hostile ways. These in turn appear to increase the probability that heavy consumers of media violence will act in hostile or aggressive ways.

Effects of Media Violence on Children's Physical Aggression

Bushman and Huesmann (2006) conducted a meta-analysis of 431 studies related to the effects of media violence, of which 264 focused specifically on children (for a total sample of 50 312 children aged 18 or younger). Studies were included if they assessed the impact of violent content in TV programs, films, video games, music, or comic books. Across this sizable body of research, both experimental and self-selected exposure to media violence were associated with negative outcomes: more aggressive behaviors, thoughts, and feelings, as well reduced helping behavior. The authors also noted that although short-term effects (measured experimentally) were somewhat stronger for adults than for children, long-term relationships between self-selected exposure and subsequent aggression (in some studies, measured years later) were stronger for exposure during childhood than during adulthood.

In one major study (Huesmann et al., 2003), over 400 US 6- to 9-year-olds were surveyed about their exposure to and interpretations of TV violence. Fifteen years later (i.e., when the participants were aged 21–23), their levels of aggression were assessed through several means: (1) interviews with the participant, (2) interviews with a spouse, close friend, or significant other, and (3) by examining criminal records. Childhood exposure to TV violence predicted individuals' physical aggression as adults. These relationships between childhood exposure and adult aggression were stronger for those who, as children, had perceived TV violence to be realistic and who had identified with same-sex aggressive TV heroes and heroines.

Effects of TV Content on Children's Non-Physical Aggression

The Huesman et al. (2003) longitudinal study of media violence also found that among women in the sample childhood exposure to TV violence predicted nonphysical aggressive acts in adulthood (e.g., trying to get someone into trouble). Other studies conducted in England and the United States have also found relationships between children's media use and their tendency to engage in various forms of nonphysical aggression (often referred to as indirect, relational, or social aggression). These types of aggression involve intentionally harming someone's social standing, often by manipulative acts such as gossiping, spreading rumors, or exclusion. In various studies, including a recent longitudinal study by Gentile et al. (2011), preteens or young teens who watched more programs featuring these forms of interpersonal hostility were more likely to engage in those behaviors themselves. There is some indication that such relationships are more likely to be observed for females than for males.

Effects of Media Racial and Gender Stereotyping

Researchers who have documented racial and gender biases in media depictions of reality have long speculated about the implications for children's feelings, beliefs, and attitudes. Content analyses of TV and magazine content in the United States continue to document underrepresentation and stereotyped representations of females and non-Anglo ethnic/racial groups. At the same time, surveys of non-Anglo children in the United States indicate a strong desire to see representations of their own group and an awareness of racial bias in news and entertainment depictions (Children Now, 1999).

Taken together, these patterns may help explain the findings of a longitudinal study conducted by Martins and Harrison (2012) with over 400 children aged 7–12 in the United States. They found that television exposure in second to fourth grade was associated with decreased self-esteem 1 year later among Anglo and African American girls and African American boys (i.e., those groups that tend to be underrepresented and misrepresented on US TV programing). In contrast, television viewing was associated with an increase in self-esteem among Anglo-American boys. These relationships were significant even after controlling for age, body satisfaction, and baseline self-esteem.

Media content may also shape children's broader beliefs about social roles, such as gender roles. Oppliger (2007) conducted a meta-analysis of 31 studies conducted in a variety of countries, examining the relationship between media use (including TV, magazine, and film use) and gender role stereotyping. Measures of stereotyping included judgments about the appropriateness of various occupations for men and women, the appropriateness of playing with sex-typed toys, estimates of the number of men and women in various occupations, and behavioral measures such as the child's own play behaviors, reported performance of gender-normative chores, and imitation of counter-stereotypical role models. Across the subset of studies dealing specifically with children, there was a small but significant relationship between exposure and stereotype-consistent beliefs, attitudes, and behaviors.

Effects of Media Use on Children's Materialism

Research has also examined the effects of exposure to advertising and other media content on children's levels of

materialism (desire for objects, beliefs that personal worth is derived from material possessions). A review of the literature by Buijzen and Valkenburg (2003) found weak to moderate relationships between children's exposure to advertising and their levels of materialism (assessed by responses to standardized items about the importance of material goods) and similar relationships between exposure to advertising and levels of parent–child conflict. However, they did not find any indication that exposure to advertising made children more unhappy. Other research has found relationships between children's exposure to advertising and their recognition of brands, their desire for advertised products, and their requests to parents for the products advertised.

Prosocial Effects of Media Exposure
